\textbf{A B S T R A C T}

A series of new peptidomimetics targeting the polo-box domain (PBD) of polo-like kinase 1 (Plk1) was identified based on the potent and selective pentapeptide Plk1 PBD inhibitor PLHSpT. Unnatural amino acid residues were introduced to the newly designed compound and the N-terminal substituent of the peptidomimetic was investigated. The optimized compound \textsuperscript{9} inhibited the Plk1 PBD with IC\textsubscript{50} of 0.267 \textmu M and showed almost no inhibition to Plk2 PBD or Plk3 PBD at 100 \textmu M. Biolayer interferometry studies demonstrated that compound \textsuperscript{9} showed potent binding affinity to Plk1 with a K\textsubscript{d} value of 0.164 \textmu M, while no K\textsubscript{d} were detected against Plk2 and Plk3. Compound \textsuperscript{9} showed improved stability in rat plasma compared to PLHSpT. Binding mode analysis was performed and in agreement with the observed experimental results. There are only two natural amino acids remained in the chemical structure of \textsuperscript{9}. This study may provide new information for further research on Plk1 PBD inhibitors.

1. Introduction

Polo-like kinases (Plks) are highly conserved families of serine/threonine protein kinases that are essential for multiple processes in the cell cycle progression, among which Plk1 is most thoroughly characterized \cite{1,2}. Plk1 regulates several key mitotic events, such as mitotic entry, centrosome maturation, spindle assembly, chromosome segregation, and cytokinesis \cite{1–3}. Plk1 is overexpressed in a broad spectrum of cancer types, which often correlates with poor prognosis \cite{4}. Overexpression of Plk1 in cancer cells, but not in normal cells, makes it an attractive and hot therapeutic target.

Among the five identified mammalian Plk family members (Plk1-5), Plk1-4 consists of an N-terminal catalytic domain and a highly conserved C-terminal domain composed of 1 or 2 highly conserved sequences, termed polo-box domains (PBDs) \cite{5,6}. PBD directs the N-terminal catalytic domain for specific subcellular localization through interacting with phosphoserine/phosphothreonine (pS/pT)-containing motifs \cite{7}.

Plk1, Plk2 and Plk3 are closely related while Plk4 is a less related kinase which apparently expressed in different patterns and showed different physiological functions \cite{4,8}. However, Plk2 and Plk3, two most closely related kinases with Plk1, appear to function as oncosgenic suppressors \cite{4,7,8}. Several potent ATP-competitive Plk1 inhibitors targeting the ATP-binding catalytic domain have been reported. However, ATP-binding pockets of Plks have high similarities, therefore it is difficult to target Plk1 specifically \cite{9}. An alternative approach for identifying potent and highly selective Plk1 inhibitors is to target the PBD which is unique and a specific signature of the Plks \cite{10}. Therefore the inhibition of Plk1 PBD is considered to be an effective method of inhibiting Plk1, which can avoid related specificity problems \cite{11,12}.

A phosphothreonine (pT)-containing pentapeptide PLHSpT (Fig. 1, 1) was identified as a potent Plk1 PBD inhibitor (Plk1 PBD \textit{Kd} = 0.445 \textmu M, no binding to Plk2 PBD) \cite{5}. After that, several phosphate peptides and peptidomimetics were reported (Fig. 1, 2–4) \cite{13–21}. A series of (2S,3R)-2-amino-3-methyl-4-phosphonobutanoic acid (Pmab) incorporated peptidomimetic analogues was also reported as a phosphatase-stable peptidomimetic with potent inhibition to Plk1 PBD \cite{22}. Representative compound (Fig. 1, 5) showed potent Plk1 inhibitory activity (Plk1 PBD \textit{IC}_{50} = 0.21 \textmu M) and high selectivity (Plk2 PBD \textit{IC}_{50} > 1000 \textmu M, Plk3 PBD \textit{IC}_{50} > 1000 \textmu M). However, these reported peptides and peptidomimetics with potent and highly selective Plk1 PBD inhibition have several issues such as limited bioavailability, and poor plasma stability, et al. \cite{19}. In our previous study, a series of \textit{o}-amino acid-containing peptidomimetics were identified as novel polo-like kinase 1 (Plk1) polo-box domain (PBD) inhibitors. Among which compound \textsuperscript{6} (Fig. 1) showed potent Plk1 inhibitory activity (Plk1 PBD...
IC50 = 0.80 µM) and high selectivity (Plk2 PBD IC50 > 100 µM, Plk3 PBD IC50 > 100 µM), together with improved stability in rat plasma compared to l-peptide inhibitor [23].

In this study, the Pro and Leu in the N-terminal and the His residue of PLHSpT were modified respectively. A series of potent and selective Plk1 PBD inhibitors with only two natural amino acid residues remained were identified.

2. Results and discussion

2.1. Design, synthesis and evaluation

The reported potent and selective pentapeptide (PLHSpT) was selected as a lead, and a series of modifications were explored in order to discover more minimal peptide. Firstly, carboxylic acid group was introduced to the N-terminal Pro-Leu residues considering there is a basic amino acid residue Arg516 in the pyrrolidine-binding region of Plk1 PBD [17]. Thus compound 7a to 7d was designed and synthesized. The four obtained compounds were evaluated using our optimized fluorescence polarization (FP) method. As shown in Table 1, the binding affinity of the four compounds to Plk1 PBD decreased dramatically. Then the N-terminal Leu was kept and modifications on the Pro was explored using the same method as the design of 7a to 7d. Compound 7e to 7h was obtained as list in Table 1. It could be found that compound 7e, in which that an L-Asp was introduced and taken the place of Pro in PLHSpT, showed comparable Plk1 PBD inhibitory activity (IC50 = 4.779 µM), while compound 8d, 8e and 8f containing a pyridine-4-yl, thiophen-2-yl and thiazol-4-yl replaced imidazole showed potent Plk1 PBD inhibitory activity with IC50 of 0.586, 0.511 and 0.441 µM respectively.

Finally, the optimized N-terminal ‘tail’ was introduced to take the place of Pro-Leu in 8f and compound 9 was obtained. Compound 9 showed almost no binding to Plk2 PBD and Plk3 PBD at 100 µM. Then, the His residue in PLHSpT was modified by changing the imidazole ring to other aromatic or heterocyclic groups and compound 8a to 8f were designed and synthesized. Compound 8a with a phenyl replaced imidazole showed moderate Plk1 PBD inhibitory activity (IC50 = 4.779 µM), while compound 8d, 8e and 8f containing a pyridine-4-yl, thiophen-2-yl and thiazol-4-yl replaced imidazole showed potent Plk1 PBD inhibitory activity with IC50 of 0.586, 0.511 and 0.441 µM respectively.

2.2. Plasma stability

The stability of PLHSpT (6) and optimized compound 9 were determined following time-dependent incubation in rat plasma using LC-MS. As shown in Fig. 3, the degradation of compound 9 is significantly (p < 0.05) slower than PLHSpT after 60 min and longer incubation. By 120 min, 73.9% of PLHSpT retained in plasma, while more than 85% of compound 9 retained in plasma.

(continued on next page)
for compound 9 remained in comparison. This result demonstrated that compound 9 have improved stability in rat plasma compared to PLHSpT (1).

2.3. Binding mode analysis

Routine methods based on molecular docking were used for analyzing the binding mode of compound 9 [24–26]. As shown in Fig. 4, consistent binding modes were found between compound 9 (yellow) and the co-crystallized ligand PLShpT (1, cyan) in structure of PDB 3HIK. The negatively charged phosphate group of phosphorylated threonine residue in the two compounds both form electrostatic interactions with Lys540 (2.9 Å, right panel in Fig. 4). The carbonyl oxygen of the N-terminal proline residue of PLShpT was in polar contact (H bond) with the guanidinium moiety of Arg516, while the newly introduced negatively charged carboxyl group in compound 9 can form an electrostatic interaction with the guanidinium moiety Arg516 (2.9 Å, left panel in Fig. 4), which enhances the binding affinity of compound 9 to Plk1 PBD.

3. Conclusion

We have designed and synthesized a series of peptidomimetics as new Plk1 PBD inhibitors. Binding affinity of the synthesized compounds was evaluated using our optimized FP assay. Among the 18 compounds obtained, 6 compounds (7e, 7k, 8d, 8e, 8f and 9) showed potent Plk1 PBD inhibitory activity with IC50 less than 1 µM. Specially, compound 9 was the most potent one which inhibited Plk1 PBD with an IC50 at 0.267 µM, and almost no inhibition to Plk2 PBD or Plk3 PBD at 100 µM. Biolayer interferometry studies demonstrated that compound 9 showed potent binding affinity to Plk1 with a $K_d$ value of 0.164 µM, while no binding detected against Plk2 and Plk3. Additionally, compound 9 had improved stability in rat plasma compared to PLHSpT (1) which confirmed our hypothesis of plasma-stable unnatural amino acid modification. Binding mode analysis was performed and it was found that the negatively charged carboxyl group introduced to the N-terminal can form an electrostatic interaction with the guanidinium moiety Arg516, which can enhance the binding affinity to Plk1 PBD. In this work, from the lead with five natural amino acids, potent and selective Plk1 PBD inhibitor with only two natural amino acids left in the structure was identified. This work can provide a new idea and method for the further research of Plk1 PBD inhibitors as potential anticancer therapy.

4. Experimental section

4.1. Chemistry

Rink amide 4-methylbenzyhydrazine resin and 9-fluorenlymethoxycarbonyl (Fmoc) amino acids were obtained from Jill Biochemical Co., Ltd. Other reagents used for peptide synthesis included trifluoroacetic acid (TFA; Aladdin Reagent Co., Ltd), piperidine (Sinopharm Chemical Reagent Co., Ltd), 1-O-benzozazole- N,N,N′,N′- tetramethyluronium hexafluoro-phosphate (HBTU; Jill Biochemical Co., Ltd), 1-hydroxybenzozazole hydrate (HOBt; Jill Biochemical Co., Ltd), and N,N- dimethylformamide (DMF, peptide synthesis grade; Tianjin Chemical Reagent Factory).

All peptides were prepared by Fmoc SPPS methods using Rink amide with an initial loading of 0.8 mmol/g unless otherwise noted. Fmoc-Ser(t-Bu)-OH and other Fmoc protected amino acids were purchased from Jill Biochemical Co., Ltd. Resins were swollen in N,N-di-methylformamide (DMF) for 30 min prior to synthesis. For sequence extension, the Fmoc-protected amino acid (3.0 equiv) was activated by treatment with HBTU (3.0 equiv), HOBt (3.0 equiv) and N,N-diisopro- pyl etheramine (6.0 equiv) in DMF (1 mL) for 2 min. This solution was added to the free amine on resin, and the coupling reaction was allowed to proceed for 1 h with vortex stirring. After washing with DMF, Fmoc deprotection was achieved with 20% piperidine in DMF (1 × 10 min, 1 × 15 min). The resin was washed once again, and the process was repeated for the next amino acid, and finally the resin was washed with DMF, dichloromethane and then dried under vacuum. Linear peptides were cleaved from the resin with 5% trisopropylsilane (TIS) and 5% H2O in trifluoroacetic acid (TFA, approximately 2 mL of TFA per 100 mg of resin) for 3 h. The cleavage mixture was mixed with cold ether to precipitate the peptide and then centrifugation. Reverse-phase HPLC analysis (RP-HPLC) was carried out on the preparative Vydac C18 column (15 μm, 20 mm × 250 mm) using an appropriate water/acetonitrile gradient in the presence of 0.1% TFA. The final purity of the peptides (> 95%) was assessed by RP-HPLC on an analytical Vydac C18 column (4.6 mm × 250 mm, 300 Å, 5 μm particle size). The molecular masses of purified peptides were determined using ESI-MS (Thermo-Finnigan, San Jose, CA, USA).

Compound 7a. HRMS (ESI-TOF) m/z calc’d for C19H30N7O12P [M + H]$^+$ 580.1846, found 580.1851, Purity > 99%; Compound 7b. HRMS (ESI-TOF) m/z calc’d for C19H30N7O12P [M + H]$^+$ 580.1846, found 580.1851, Purity > 99%; Compound 7c. HRMS (ESI-TOF) m/z calc’d for C20H32N7O12P [M + H]$^+$ 594.1936, found 594.1931, Purity > 99%;
4.2. Fluorescence polarization (FP) assays

The binding experiments were performed on a SpectraMax MultiMode Microplate Reader ( Molecular Devices) using the excitation at 485 nm and emission filters at 535 nm, respectively. In the fluorescence polarization assays, FP was determined by measuring intensities (Intperpendicular, F⊥) and the parallel fluorescence intensities (Intparallel, F∥) as previously described [27]. The interactions of the compound 9 with Plk1, Plk2 and Plk3 protein were detected by biolayer interferometry using an Octet Red 96 instrument (FortéBio, MenloPark, CA, USA). Plk1, Plk2 and Plk3 protein were biotinylated with one molar ratio using EZ link sulfo-NHS-LS-biotinylation kit (#21340, Thermo Pierce). Super Streptavidin biosensors tips (FortéBio, Inc., Menlo Park, CA) were prewetted with BLI kinetics buffer (PBS, 0.05% BSA, 0.01% Tween-20) for 10 mins to establish a baseline before immobilization.

Then biotinylated protein was bound by dipping SSA sensors into biotinylated Plk1, Plk2 or Plk3 protein (a final concentration of 200 nM). The interactions of the compound 9 prepared in BLI kinetics buffer was immobilized onto SSA sensors. All of the binding data were collected at 30 °C. The experiments comprised five steps: (1) baseline acquisition (60 s), (2) protein loading onto the sensor (1000 s), (3) second baseline acquisition (120 s), (4) association of compound for the measurement of k_on (150 s), and (5) dissociation of compound for the measurement of k_off (150 s). Baseline and dissociation steps were performed in buffer only. The association and dissociation plot and kinetic constants (k_on and k_off) were step corrected, reference corrected, fit globally to a 1:1 binding model and automatically obtained with Octet data analysis software (7.1). Equilibrium dissociation constants (K_d) were calculated by the ratio of k_off to k_on.

4.4. Plasma stability

One milliliter of rat plasma was mixed with 0.1 mL compound 6 or compound 18 solution to make a final concentration of 10 μg·mL⁻¹. The mixture was incubated at 37 °C. An aliquot of 100 μL solution was taken at different time interval and mixed with 300 μL of methanol acetonitrile (50:50, v/v) to precipitate plasma proteins. After vortexed and centrifuged at 4 °C for 20 min at 12,000 rpm. The supernatant was transferred and determined with LC-MS.

The LC-MS analysis was performed by a Thermo TSQ Quantis LC-MS/MS system (Thermo, US), consisting of a binary pump solvent management system, an online degasser, an autosampler, and a TSQ Quantum mass spectrometry. The chromatographic separation was performed with an Inertsustain C18 column (150 × 4.6 mm, 5 μm) with a gradient mobile phase of 0.1% formic acid in water (solvent A) and 0.1% formic acid in acetonitrile (solvent B). The gradient program was performed with an InertSustain C18 column (150 × 4.6 mm, 5 μm) with a gradient mobile phase of 0.1% formic acid in water (solvent A) and 0.1% formic acid in acetonitrile (solvent B). The gradient program was as follows: 0 min 5% B; 8 min 30% B; 8.2 min 80% B; 9 min 80% B; 9.1 min 5% B; 15 min 5% B, and the flow rate was 1 mL min⁻¹. All the samples were studied with an injection volume of 20 μL.

Positive electrospray ionization (ESI) mode was used for the MS determination, with the source parameters were as follows: spray voltage, 4000 V; transfer tube temperature, 350 °C; sheath gas 30 Arb; ion sweep gas pressure 1.0 psi.

4.5. Molecular modeling

In this study, Autodock 4.2 with Lamarckian genetic algorithm (LGA) was employed for molecular docking due to its good performance in reproducing the binding mode of a ligand to its target [24]. The PDB structure of 3HIK was used as the receptor for molecular docking. The Gasteiger partial charge was assigned to the system of interest. The docking space was set to 18.75 × 18.75 × 18.75 Å (corresponding to 50 × 50 × 50 grids, with each grid 0.375 Å in length) for sufficient sampling. Each ligand was docked for 50 times to derive the most stable docking pose for analysis.
