Investigation of phytoplankton from East China Sea of the Pacific Ocean, offshore Réunion Island of the Indian Ocean, and the French Atlantic coast revealed a species of poorly known armored fusiform dinoflagellate. To clarify this species, morphology and phylogeny based on mitochondrial and nuclear protein gene sequence (Cox1, Cob and Hsp90) concatenated with the SSU, ITS region and LSU rDNA sequences were analysed. Epifluorescence and scanning electron microscopy observations revealed that the nucleus of the specimen was elongated, sausage-shaped and located equatorially on the left lateral side of the cell, and that the plate formula is Po, 3', 1a, 6'', 6C, 8S, 5''', 1p, 2'''''. These morphological features indicate that the species can be assigned to *Centrodinium punctatum*. Interestingly, the phylogenetic analyses placed this species within the *Alexandrium* clade, with *Alexandrium affine* being its closest relative. This indicates that genus *Alexandrium* is not monophyletic. The most similar morphological traits between *C. punctatum* and *Alexandrium* species were the shape of apical pore plate and the arrangement of the sulcal plates. However, since there are significant morphological differences between *C. punctatum* and *Alexandrium* species, further studies are needed to clarify the relation between the morphology and molecular phylogeny of other *Centrodinium*-related fusiform species.

Introduction

Dinoflagellates are a large group of protists (estimated 2,377 species) that are ubiquitous in marine environments (Gómez 2012; Taylor 1987). They are commonly divided into armored and unarmored forms (e.g., Dodge 1982; Fensome et al. 1993; Kofoid and Swezy 1921). The armored dinoflagellates possess a series of relatively rigid thecal plates and their classification is primarily based on the number and arrangement of the thecal plates (e.g., Fensome et al. 1993; Taylor 1976) and is largely corroborated by molecular phylogeny (e.g., Janoušková et al. 2017; Saldarriaga et al. 2001). However, the classification based on the morphological characters of some species is sometimes incongruent with the phylogenetic position inferred from ribosomal DNA (rDNA) sequencing data, creating uncertainty about the taxonomic status of the targeted species.

Over the past twenty years, detailed evaluations of morphology combined with molecular phylogenetic studies of dinoflagellates have resulted in descriptions of new species and re-classification of existing species (e.g., Daugbjerg et al. 2000; Hoppenrath et al. 2009; John et al. 2014; Li et al. 2015, 2017). In particular, highly conserved molecular markers such as ribosomal DNA (rDNA) are most informative for the resolution of relationships between terminal nodes in phylogenetic trees (Hoppenrath 2017). Recently, in addition to rDNA gene sequencing, the use of mitochondrial and nuclear protein genes, such as cytochrome c oxidase I (Cox1), cytochrome b (Cob) and heat shock protein 90 (Hsp90), have clarified the relationships between morphological characters and the phylogenetic placement of dinoflagellates (e.g., Hoppenrath and Leander 2010; Lin et al. 2009).

Among marine armored dinoflagellates, some species characterized by a unique fusiform shape are gonyaulacoid, and belong a.o. to the genera *Centrodinium* Kofoid, *Gonyaulax* Diesing, *Pavillardinium* de Toni, *Schuetiella* Balech and *Spiraulax* Kofoid (e.g., Balech 1962; Carbonell-Moore 1996; Hernández-Becerril et al. 2010; Taylor 1976). Armored fusiform dinoflagellates have rarely been reported, and their morphology and distribution are poorly known. As a consequence, the taxonomic status of the fusiform dinoflagellates has been continuously revised (e.g., Carbonell-Moore 1996; Hernández-Becerril et al. 2010; Kofoid 1907; Sournia 1986), and molecular data have not been obtained, except for the cyst-based taxon *Dapsilodinium pastielsii* (Davey & Williams) Bujak, Downie, Eaton & Williams (Mertens et al. 2014).

One of the armored fusiform dinoflagellate genera, the genus *Centrodinium* Kofoid, was erected in 1907, with *Centrodinium elongatum* Kofoid as the type species (Kofoid 1907), but no thecal plate formula was given in the original description. The genus *Centrodinium* strongly resembles some species previously assigned to *Pavillardinium* [e.g., *P. punctatum* (Cleve) de Toni], and for this reason, Taylor (1976) transferred five *Centrodinium*-like *Pavillardinium* species to the genus *Centrodinium*. The genus *Pavillardinium* was erected to replace the genus *Murrayella* Kofoid by de Toni (1936), because the genus *Murrayella* was already preoccupied by the red algal genus *Murrayella* Schmitz (Kofoid 1907; Schmitz 1893). Currently, 18 species are assigned to the genus *Centrodinium* which includes some previously recorded *Murrayella* and *Pavillardinium* species (Guiry and Guiry 2018). Most *Centrodinium* species are distributed in tropical to temperate regions, e.g., the north-eastern Atlantic Ocean (Okolodkov and Dodge 1997), the Indian Ocean (Taylor 1976), and the Mexican Pacific coast (Hernández-Becerril et al. 2010). However, despite such records on the distribution of *Centrodinium* species, morphological observations of many *Centrodinium* species, including its type, are incomplete and accordingly, the classification of *Centrodinium* is currently unclear and remains untested with molecular phylogenetic data.

During a study of field samples from the East China Sea with the purpose to document the diversity of marine dinoflagellates, a poorly known armored fusiform dinoflagellate was encountered, and a culture was successfully established. With the aim to identify this fusiform dinoflagellate, this culture was examined by light and scanning electron microscopy, and the small subunit (SSU) rDNA, internal transcribed spacer 1 (ITS1) and ITS2, 5.8S rDNA, partial large subunit (LSU) rDNA and nuclear protein gene sequence (Cox1, Cob and Hsp90) were sequenced. The aim was to understand how this species compared to *Centrodinium punctatum* (Cleve) Taylor and its relation to other gonyaulacoid genera such as *Alexandrium*. In addition, the SSU rDNA sequencing data were compared to sequences of two morphologically similar specimen obtained from the French Atlantic coast.

Results

On the basis of the morphological and molecular results presented herein (Figs 1–10; Appendix S1), the present species is identified as *Centrodinium punctatum*, and the SSU, ITS region, LSU, Cox1,

Cob and Hsp90 gene sequences of this species were deposited in GenBank (Appendix S2).

Morphology of *Centrodinium punctatum*

Living cells were solitary, broadly fusiform and yellow in color (Fig. 1A–F). The cells were 40.7–80.6 μm (average = 62.4 μm , $n=50$) in length, 19.5–40.9 μm (average = 31.2 μm , $n=50$) in width, and 21.4–39.9 μm (average = 29.7 μm , $n=50$) in depth (dorso-ventral axis), with an average width-to-depth ratio of ~ 1.1 . The epitheca was prolonged in an apical horn, $\sim 43\%$ of the total length of the body, measured from the proximal end of the cingulum. The hypotheca also extended into a horn and it was longer than the epitheca, $\sim 54\%$ of the total length of the body, measured from the distal end of the cingulum. The cingulum descended by about one cingulum width (Fig. 1A).

The sulcus was not broader than the cingulum. The thecal surface was strongly areolated, which was visible under a light microscope (Fig. 1A, C, F). One or two pusules were visible in the cell (Fig. 1B, E). Cells contained numerous chloroplasts (Fig. 1G, H). The nucleus was elongated, sausage-shaped and located on the left-lateral side of the cell (Fig. 1G, H).

The thecal morphology of *Centrodinium punctatum* collected from East China Sea and offshore Réunion Island, Indian Ocean is shown in Figures 2–8. The cells displayed a plate formula of Po, 3', 1a, 6'', 6C, 8S, 5''', 1p, 2'''' (Figs 2–8). The typical plate pattern is illustrated in Figure 8. The epitheca was composed of the apical pore plate (Po), three apical plates (3'), one anterior intercalary plate (1a), and six precingular plates (6'') (Figs 2, 3, 7). The Po plate was slightly sunken

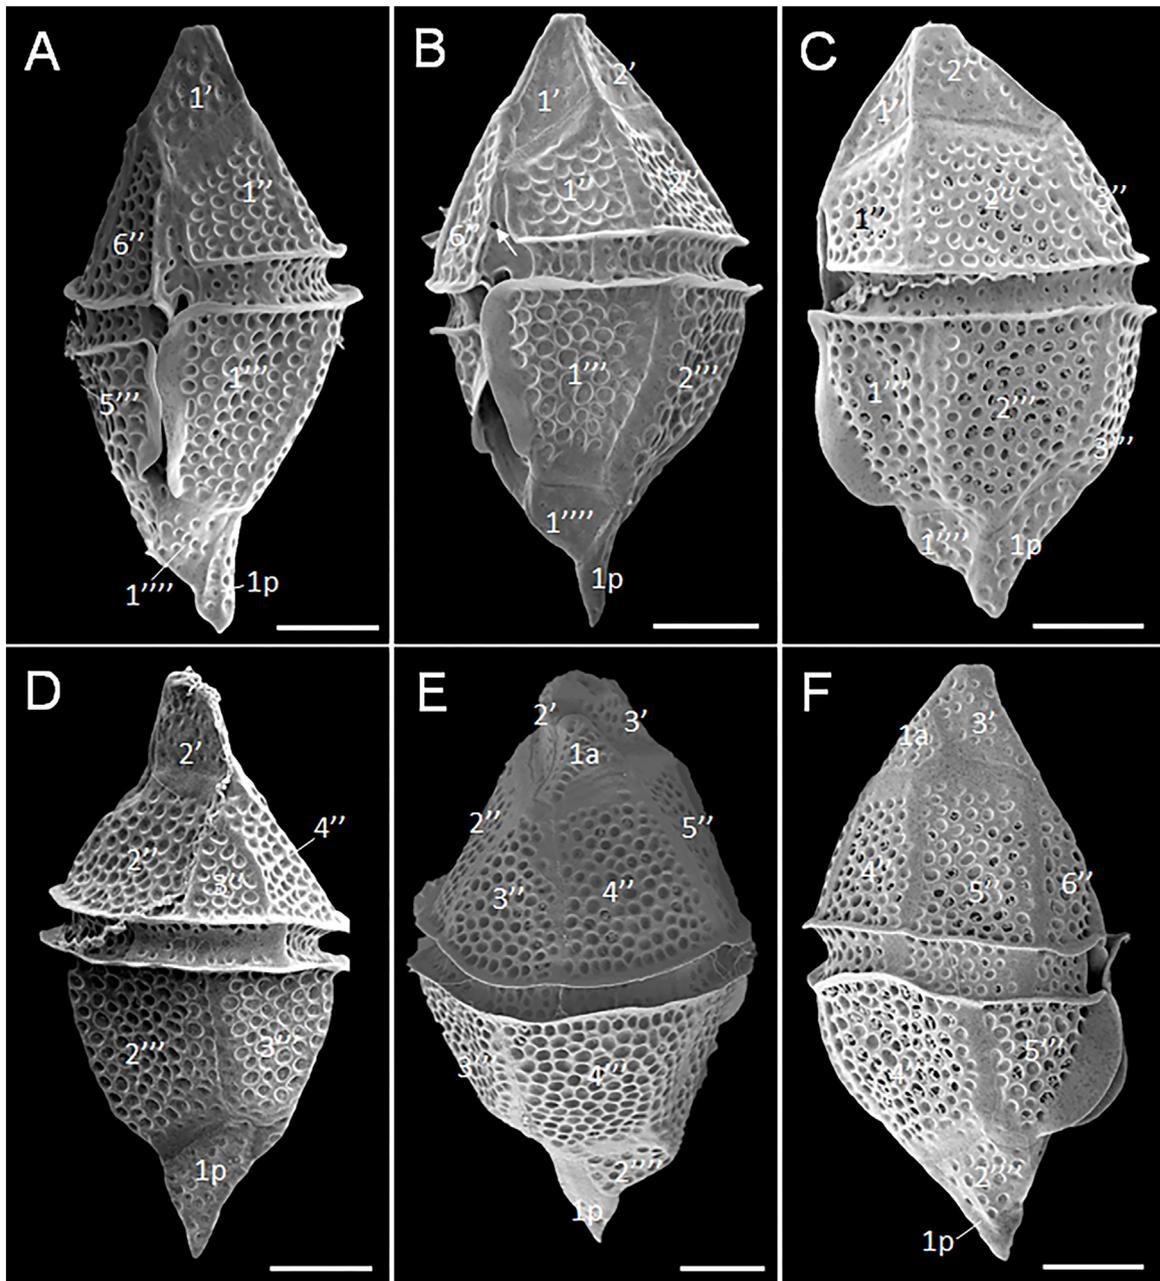

Figure 2. Scanning electron micrographs of *Centrodinium punctatum*. Material from culture strain LIMS-PS-2525. (A) Ventral view. and enclosed by the surrounding plates and located centrally at the apex (Figs 3B, D, 7E, F). The Po contained a horseshoe-shaped apical pore (foramen), and an elongated callus. The apical pore was surrounded by a row of marginal pores of equal sizes (Figs 3D, 7F). The first apical plate (1') was pentagonal and contacted the Po and the 2', 3', 1'' and 6'' plates (Figs 2A–C, 3A, B, 7A, E). Plate 2' was

heptagonal in shape, and larger than Plate 1' (Figs 2B–D, 3B, 7E). Plate 3' was hexagonal in shape and contacted the Po, 1', 2', 1a, 5'' and 6'' plates (Figs 2F, 3A, 7D, E). Plate 1a was pentagonal in shape and smaller than Plates 2' and 3' (Figs 2E, 3B, C, 7C–E). Six precingular plates were arranged asymmetrically (Figs 2A–C, 3A, B, 7C, E). Plates 1'' and 6'' were hexagonal in shape (Figs 2A–C, 3A, B,

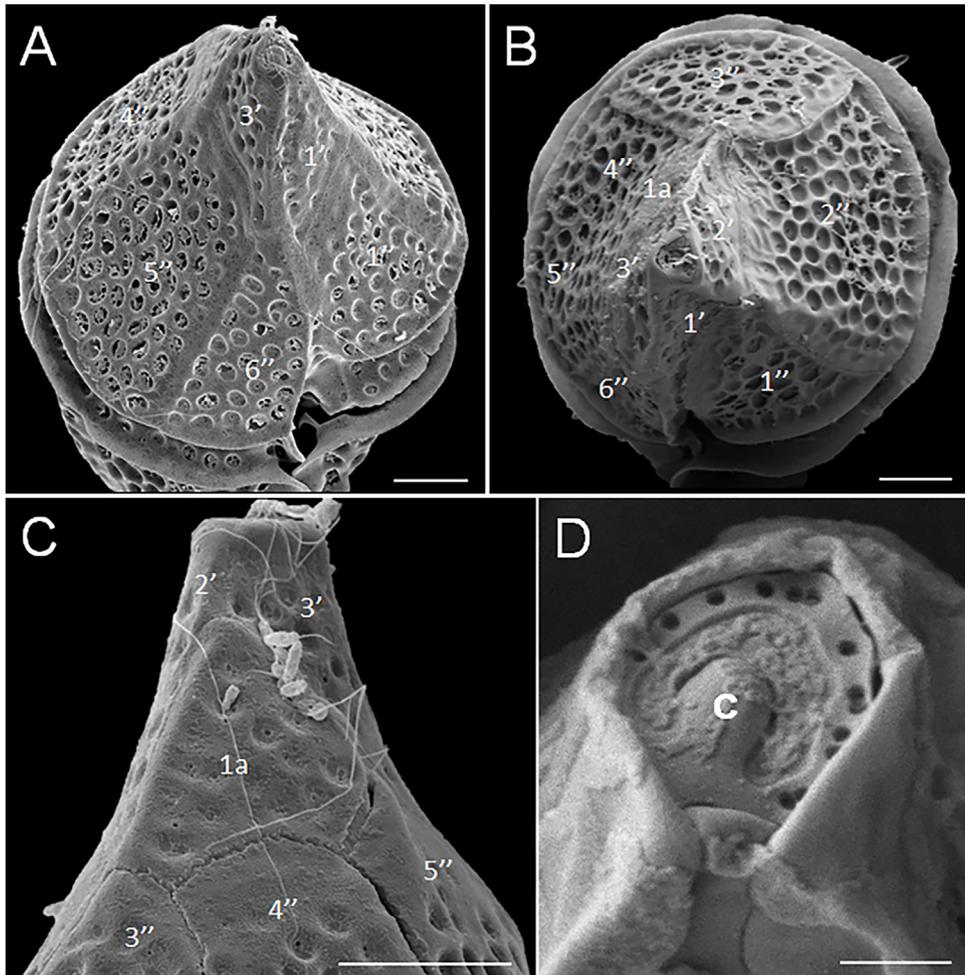

Figure 3. Details of the epithelial plates of *Centrodinium punctatum* in scanning electron micrographs (culture strain LIMS-PS-2525). (A) Ventral view showing the shape of the first apical plate 1'. (B) Apical view showing the apical, anterior intercalary and precingular plates. (C) Dorsal view showing the shape of the intercalary plate 1a. (D) Apical pore plate containing a horseshoe-shaped apical pore (foramen), and an elongated callus (c). Scale bars: A–C = 5 μ m; D = 1 μ m.

7C, E). Plates 2'' and 4'' were four-sided in shape (Figs 2C, E, 3B, 7B, C). Plates 3'' and 5'' were pentagonal in shape (Figs 2D–F, 3A, B, 7C, E). Plate 6'' was narrow and smaller than Plate 1'' (Figs 2A, 3A, 7A). The cingulum was deeply excavated, formed by six plates and descending by about one cingulum width (Fig. 4A–D). The C1 plate of the cingular series was the smallest and encroached on the left-hand side of the anterior sulcal area (Fig. 4A). The C2 plate was in contact with the C1, C3, 1'', 2'', 1''' and 2''' plates (Fig. 4A, B). Plate C3 was the largest of the cingular plates (Fig. 4B, C). The suture of plate C2 with plate C3 was located after the sutures of Plates 1'' and 2'' on the epitheca and plates 1''' and 2''' on the hypotheca (Fig. 4B). The suture of plate C3 with plate C4 was located before

the sutures of plates 3'' and 4'' on the epitheca and plates 3''' and 4''' on the hypotheca (Fig. 4C). Plate C6 was smaller than plate C5 (Fig. 4D). In the hypotheca, there were five postcingular plates (5'''), two antapical plates (2'''), and one posterior intercalary plate (1p) (Fig. 5A–D). The postcingular plates were symmetrically arranged (Fig. 5A). Plate 1''' with a well-developed list on its right-hand side was smaller than plate 2''', and contacted plate 1'''' (Fig. 5A, B). Plates 2''' and 4''' were pentagonal in shape and contacted one of the antapical plates, and plate 1p (Fig. 5A–D). Plate 3''' was symmetrical and trapezoidal in shape (Fig. 5A). The posterior margin was very narrow and contacted plate 1p (Fig. 5B, D). Plate 5''' had a well-developed list on its left-hand side and was smaller than

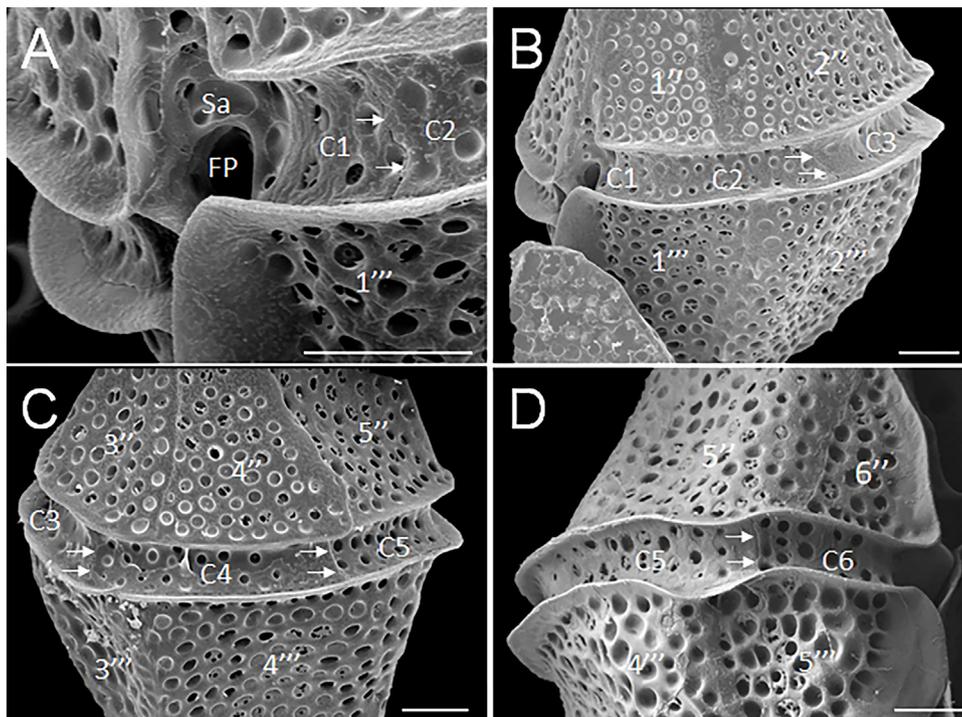

Figure 4. Details of the cingular plates of *Centrodinium punctatum* in scanning electron micrographs (culture strain LIMS-PS-2525). Small arrows indicate the five sutures separating the six cingular plates (C1–C6). FP: flagellar pore; Sa: anterior sulcal plate. Scale bars: A–D = 5 μ m.

plate 4''' (Figs 2E, F, 5A). The anterior margin of plate 5''' was wide and contacted the C5 and C6 plates (Fig. 4D). The posterior margin of plate 5''' was narrow and contacted plate 2''' (Fig. 5A). The antapical plates, 1''' and 2''', were pentagonal in shape, dissimilar in size, smaller than the five postcingular plates, and contacted the posterior sulcal area (Fig. 5A–C). Plate 1p was pentagonal in shape, and surrounded by three postcingular plates and two antapical plates: 2''', 3''' and 4''', 1''' and 2''' (Fig. 5A–D). The sulcus was narrow, with well-developed lists on both sides (Figs 2A, 7A). The sulcus consisted of eight plates (Fig. 6A–D). The anterior sulcal plate (Sa) was long and large, located between plates 1'' and 6'', with a convex posterior margin (Fig. 6A). A ventral pore was on the plate Sa (Figs 2B, 6A). Sometimes the ventral pore could hide below the bended rim of plate 6'' and seem absent (Figs 6B, 7A). The right anterior sulcal plate (Sda) was larger than the Ssa, and connected to the 6'', C6 and Sa plate (Fig. 6B, D). The left anterior sulcal plate (Ssa) was short and pentagonal in shape and did not connect to the C1 plate (Fig. 6D). The anterior median sulcal plate (Sma) and posterior median sulcal plate (Smp) were very small, located between the Ssa and the Sda (Fig. 6D). The right posterior sulcal plate (Sdp) and left posterior

sulcal plate (Ssp) were narrow and more than twice as long as they were wide (Fig. 6D). The posterior sulcal plate (Sp) was narrow, symmetrically hexagonal, extended into the hypotheca without reaching the antapex (Fig. 6C). The external theca surface of the most cells was strongly areolated (Fig. 6E) and the internal surface of the theca was smooth (Fig. 6F). The areolae were irregular ellipsoid; at the bottom of the some areolae were 2–14 small pores 0.1–0.3 μ m in diameter ($n=50$) (Fig. 6E, F).

Molecular Phylogeny

Concatenated SSU-ITS1-5.8S-ITS2-LSU

The tree inferred from the concatenation of the SSU-ITS1-5.8S-ITS2-LSU sequences showed that *C. punctatum* is nested within the *Alexandrium* clade (Fig. 9). Maximum likelihood and Bayesian inference analyses generated four similar trees that differed with respect to only a few topological features (Fig. 9; Appendix S1). In this phylogeny, *C. punctatum* and *Alexandrium* species formed a clade with 100% ML bootstrap support and 1.00 Bayesian PP (Fig. 9). The closest relative of *C. punctatum* was *Alexandrium affine* (H.Inoue & Y.Fukuyo) Balech, which formed a well-supported clade with 99% ML bootstrap support and 1.00

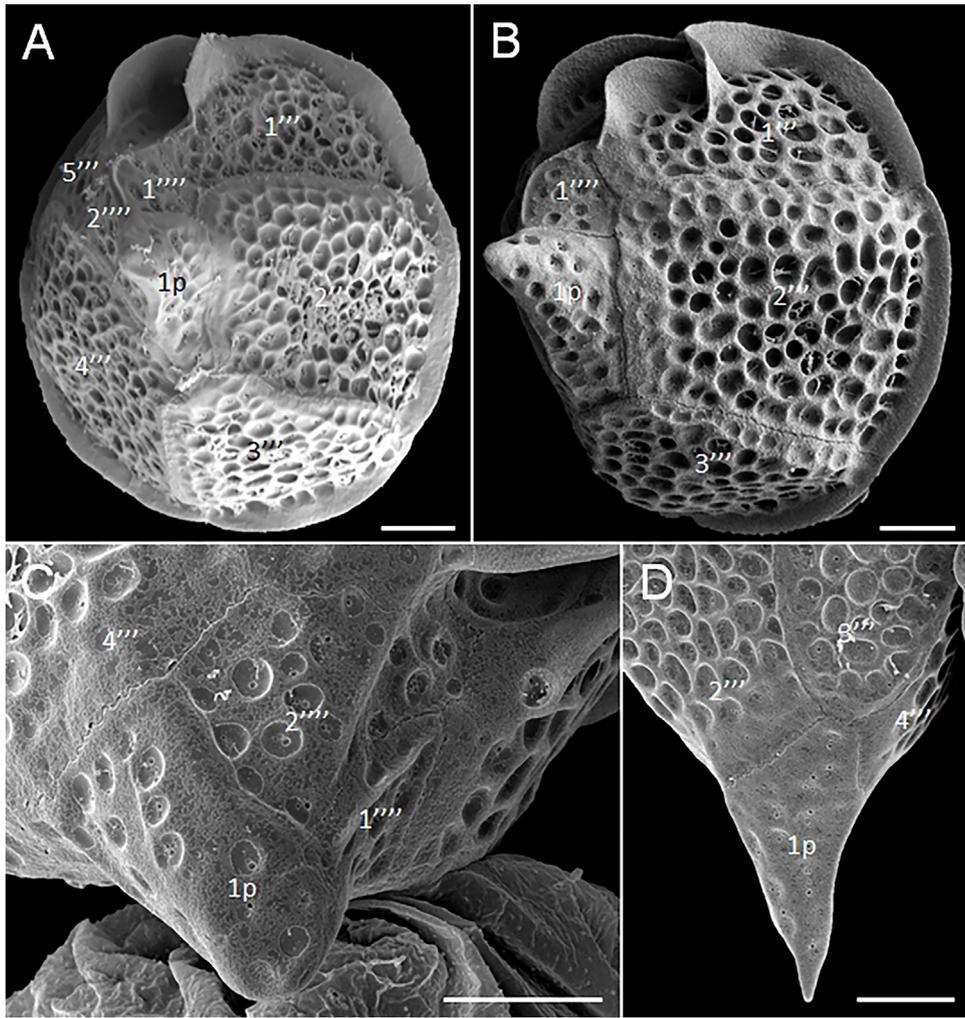

Figure 5. Details of the hypothecal plates of *Centrodinium punctatum* in scanning electron micrographs (culture strain LIMS-PS-2525). (A–B) Antapical view showing the antapical and postcingular plates. (C–D) Details of the antapical area showing the shapes of the two antapical plates and 1p plate. Scale bars: A–D = 5 μ m.

Bayesian PP. The clade of *C. punctatum* and *A. affine* was closely related to the clade of members of the *Alexandrium tamarense* species complex (100% ML bootstrap support and 1.00 Bayesian PP). The well-supported clade consisting of *C. punctatum* and *Alexandrium* species was sister to the clade with *Triadinium* Pouchet and *Gambierdiscus* Adachi & Fukuyo (100% ML bootstrap support and 1.00 Bayesian PP).

The individual gene trees (SSU, LSU and ITS) resulted in a same pattern as observed in the multiple genes trees (Appendix S1). In a phylogenetic tree based on the SSU rDNA sequence, two Korean and two French strains of *C. punctatum* formed a monophyletic group with the highest support (100% ML bootstrap support and 1.00 Bayesian PP) (Appendix S1).

Concatenated SSU-ITS1-5.8S-ITS2-LSU-Cox1-Cob-Hsp90

The phylogenetic position of *C. punctatum* was also inferred from SSU-ITS1-5.8S-ITS2-LSU-Cox1-Cob-Hsp90 gene sequences obtained in the present study (Fig. 10); the sequence accession numbers are shown in Appendix S2. Maximum likelihood and Bayesian inference analyses generated four similar trees that differed with respect to only a few topological features (Fig. 10). The dinoflagellates were found to be a monophyletic group with 100% ML bootstrap support and 1.00 Bayesian PP. Of the dinoflagellates included in the analyses, the earliest diverging was found to be *Noctiluca scintillans* (Macartney) Kofoid & Swezy. The order of Gonyaulacales was resolved as monophyletic with significant bootstrap support

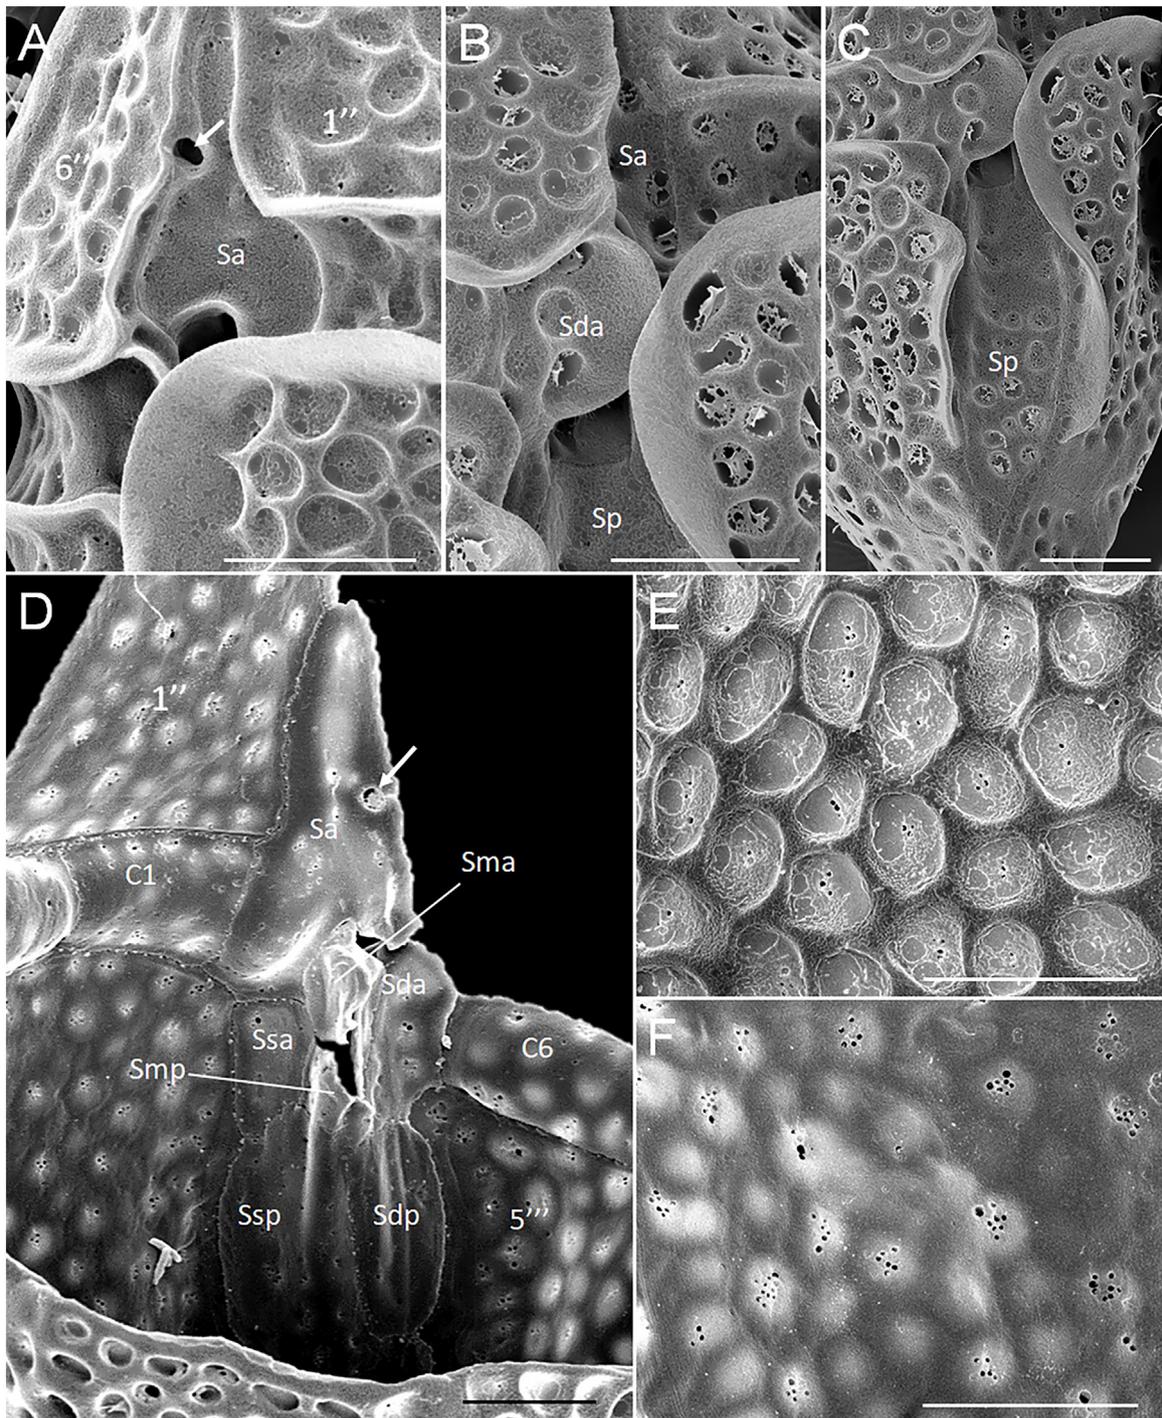

Figure 6. Details of the sulcal plates and surface morphology of *Centrodinium punctatum* (culture strain LIMS-PS-2525) in scanning electron micrographs. (100% ML bootstrap support and 1.00 Bayesian PP). *C. punctatum* was also nested within the *Alexandrium* clade and the two strains formed a subclade with 100% ML bootstrap support and 1.00 Bayesian PP. *C. punctatum* was sister to *Alexandrium affine*, which formed a well-supported clade with 100% ML bootstrap support and 1.00 Bayesian PP. The clade of *C. punctatum* and *A. affine* formed a sister clade to members of the *Alexandrium tamarense* species complex. This phylogenetic analyses also indicated that *Alexandrium* was not monophyletic (100% ML

bootstrap support and 1.00 Bayesian posterior probability [PP]).

Discussion

Morphological Comparison of *Centrodinium punctatum* with Other Fusiform Dinoflagellates

Historically, armored fusiform dinoflagellates have been classified primarily on the basis of morpho-

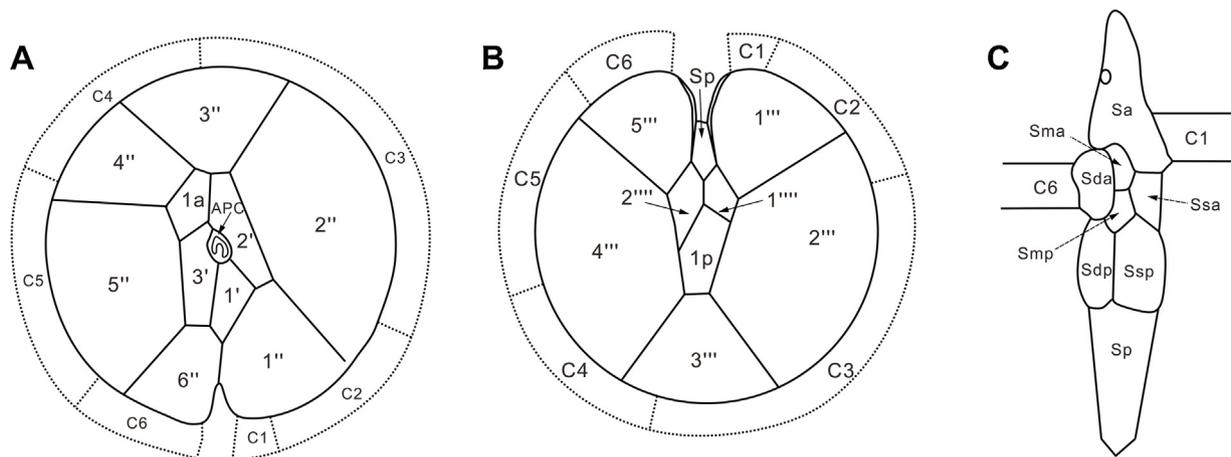

Figure 8. Diagrammatic reconstructions of *Centrodinium punctatum*. (A) Apical view. (B) Antapical view. (C) Sulcal area.

logical features, such as cell size, plate formula and cingulum offset (e.g., Balech 1962; Carbonell-Moore 1996; Hernández-Becerril et al. 2010; Kofoid 1907; Sournia 1986; Taylor 1976). The external shape of *C. punctatum* is quite similar to those of the fusiform dinoflagellates *Gonyaulax birostris* Stein and *Spiraulax jolliffei* (Murray & Whitting) Kofoid re-described by Carbonell-Moore (1996). However, the cell sizes of *G. birostris* and *S. jolliffei* (> 100 μm in length) are much larger than *C. punctatum*. The cingulum of *C. punctatum* is displaced by only one cingular width, whereas the cingulum displacement of *Gonyaulax* and *Spiraulax* species is more than one cingular width. In addition, *G. birostris* and *S. jolliffei* have two anterior intercalary plates and six postcingular plates (Carbonell-Moore 1996), whereas *C. punctatum* has only one anterior intercalary plate and five postcingular plates.

Although *C. punctatum* belongs to the genus *Centrodinium*, the morphological features of *C. punctatum* differ significantly from other *Centrodinium* species (e.g., Balech 1962; Böhm 1933; Hernández-Becerril et al. 2010; Kofoid 1907; Léger 1973; Pavillard 1930; Rampi and Bernhard 1980; Schiller 1937; Sournia 1986; Steidinger and Tangen 1997; Taylor 1976); most *Centrodinium* species are usually large (>200 μm in length) and strongly compressed laterally, with a delicate theca without areolation, whereas *C. punctatum* has a strongly areolated theca, relatively small size, and is not compressed laterally.

The thecal plate formula of *C. punctatum* has been interpreted differently (e.g., Schiller 1937; Balech 1962; Hernández-Becerril et al. 2010). The plate formula of *C. punctatum* provided by Schiller (1937) was 2' (or 4'), 0a, 5'', 5''', 1p, 4''', how-

ever Wood (1954) suggested the possible presence of an anterior intercalary plate (1a). Later, Balech (1962) suggested the presence of three anterior intercalary plates and five cingular plates, and considered the correct formula to be 2', 3a, 7'', 5C, 5''', 1p, 1'''. Later, Balech (1971) demonstrated the presence of a Po plate in *C. punctatum* and also variable development of sulcal lists and a strongly ornamented theca. Sournia (1986) suggested an approximate formula for the genus *Centrodinium*: Po (?), 2–3', 1–3a, 6–7'', 5–6C, ?S, 5''', 1–2p, 1'''. Okolodkov and Dodge (1997) studied *C. punctatum* using SEM and found a tabulation that is different from what was found in this study (Po, 3', 0a, 6'', 6'', 1p, 1'''): they did not recognize any anterior intercalary plates, but recorded six postcingular plates. Since the authors express doubt about their interpretation of the tabulation, their specimens could represent the same species as the one observed in this study.

Based on SEM observations, Hernández-Becerril et al. (2010) proposed the plate formula of *C. pulchrum* (Po, 3', 3a, 6'', 6C, 5S, 5''', 2p, 1'''), and extended it to other species of the genus *Centrodinium*. Accordingly, *Centrodinium* species described in previous studies have one or three anterior intercalary plates and only four or five plates in the sulcus (e.g., Hernández-Becerril et al. 2010; Sournia 1986). However, in contrast to *C. pulchrum*, *C. punctatum* has only one anterior intercalary plate that is not particularly laterally flattened. In addition, the cingular plates of *C. pulchrum* are almost equal in size, whereas the C1 plate of *C. punctatum* is very small (Balech 1967; Hernández-Becerril et al. 2010). On the basis of morphological differences between *C.*

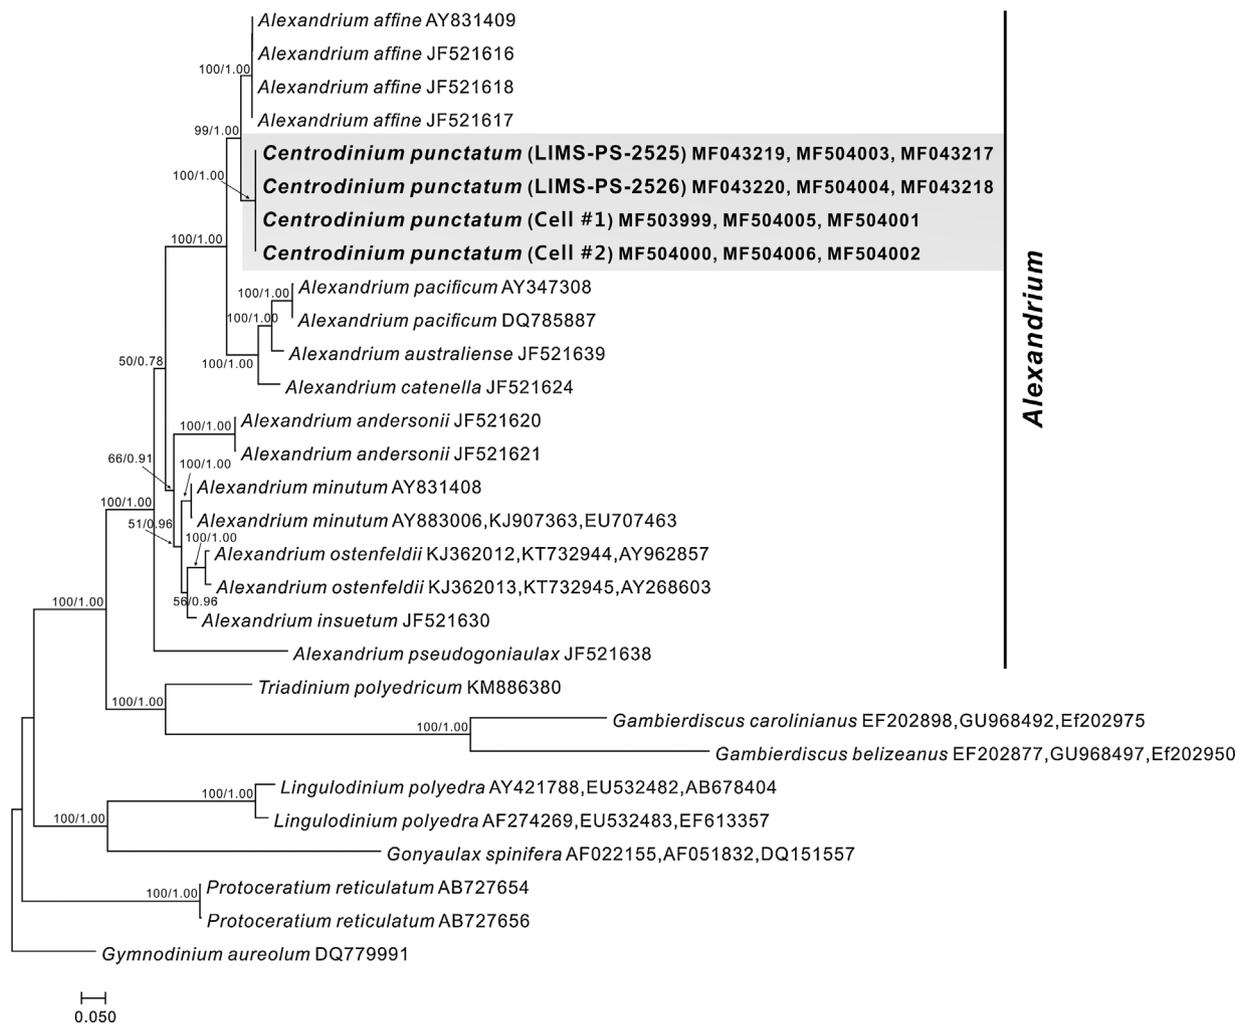

Figure 9. Maximum likelihood (ML) tree showing the phylogenetic position of *Centrodinium punctatum* (in bold) based on SSU+ITS1+5.8S+ITS2+LSU concatenated sequences (3724 bp). The unarmed dinoflagellate *Gymnodinium aureolum* (DQ779991) were used as the outgroup. The numbers on each node are the bootstrap values (%) followed by the Bayesian posterior probability (PP). Only bootstrap values above 50% and PP above 0.7 are shown. The GenBank accession number follows taxon name. Scale bar = 0.05 nucleotide substitutions per site..

punctatum and other *Centrodinium* species, *C. punctatum* may be considered as a distinct species from other *Centrodinium* species. However, since the tabulation of many *Centrodinium* species, including the type species *C. elongatum*, is lacking or incomplete, further observations of *Centrodinium* species, specifically the type, are needed to confirm the assignment of *C. punctatum* to *Centrodinium*.

Unexpected Phylogenetic Position of *Centrodinium punctatum*

Interestingly, despite the fact that the morphological features of *C. punctatum* are quite similar to those of

other fusiform dinoflagellates, the eight-gene phylogenies, and the individual gene analysis based on SSU, ITS region (ITS1, ITS2 and 5.8S rDNA) and LSU rDNA sequences revealed that *C. punctatum* shows a close relationship with the *Alexandrium* clade (Figs 9–10, Appendix S1), and that *C. punctatum* displays the closest genetic resemblance to *A. affine*. The phylogenetic placement of *C. punctatum* begs the question whether this species produces paralytic shellfish toxins (PST). For that reason, the A1 and A4 domains of the *sxtA* gene were amplified using the methods of Stüken et al. (2011), the result however revealed that Korean strains lack the saxitoxin genes (unpublished data). According to Orr

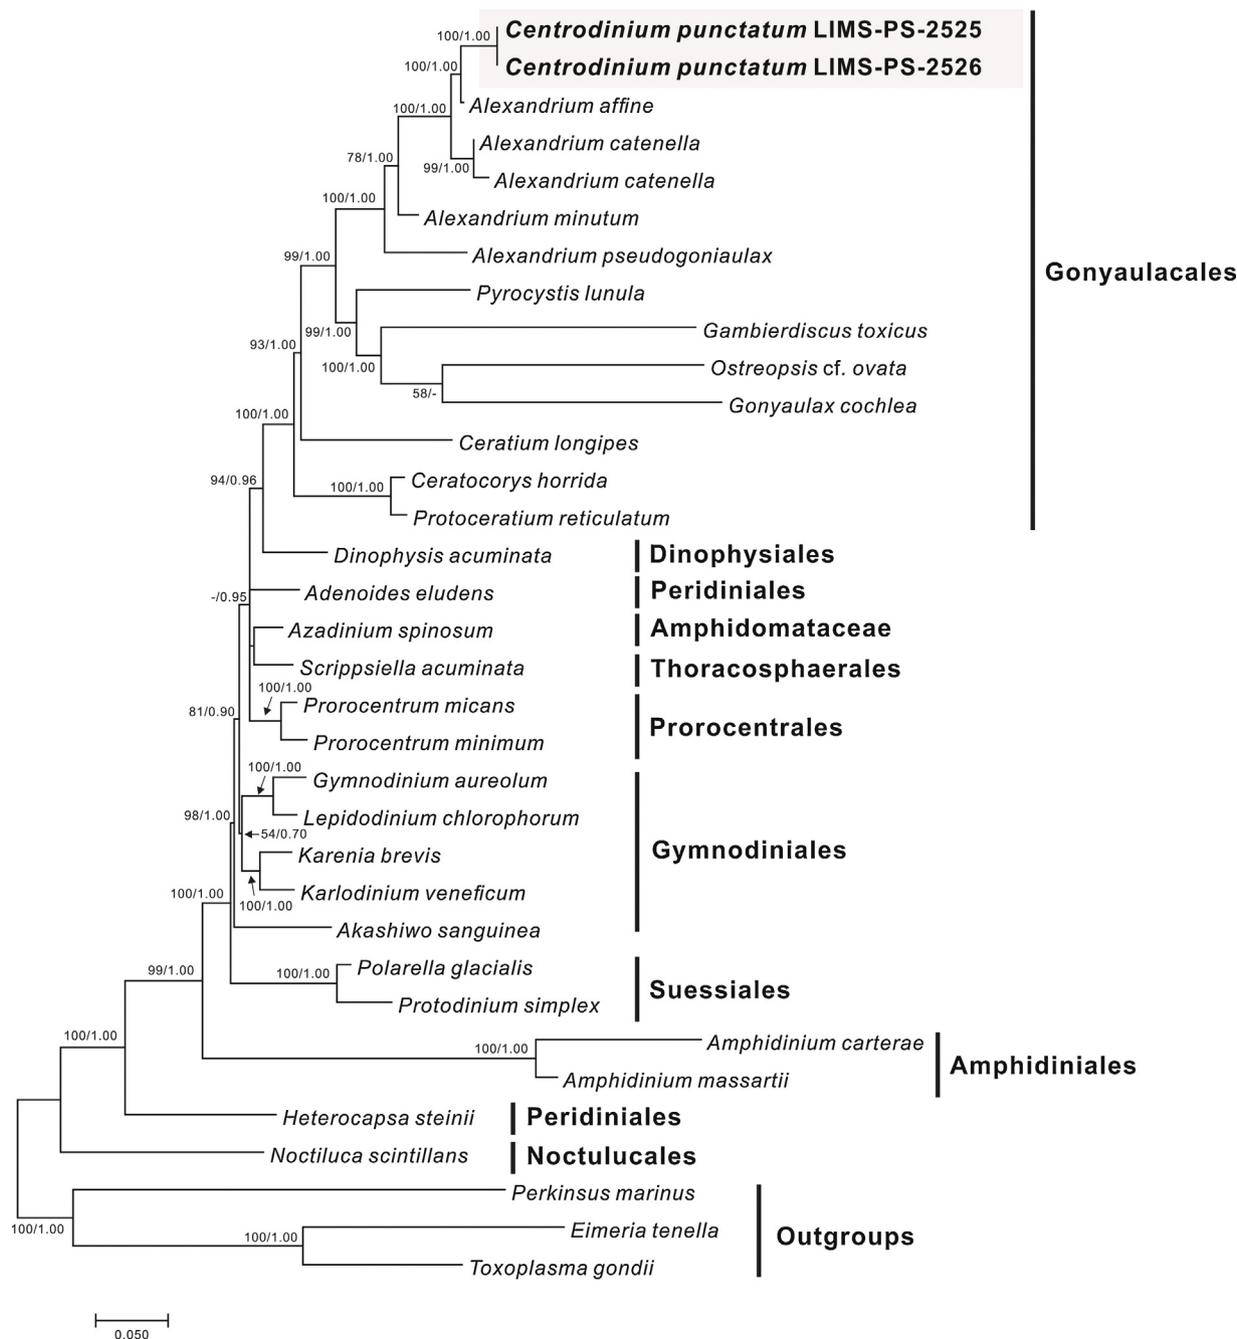

Figure 10. Maximum likelihood (ML) tree showing the phylogenetic position of *Centrodinium punctatum* (in bold) based on SSU-ITS1-5.8S-ITS2-LSU-Cox1-Cob-Hsp90 concatenated sequences (7394bp). The sequences of the Perkinsozoan species was used as the outgroup. The numbers on each node are the bootstrap values (%) followed by the Bayesian posterior probability (PP). Only bootstrap values above 50% and PP above 0.7 are shown. See Table S4 for a full listing of accessions used. Scale bar = 0.05 nucleotide substitutions per site.

et al. (2011) and Murray et al. (2014), *A. affine* is a non-STX producing species at the base of the clade containing most of the PST producing *Alexandrium* species. The close genetic relationship between *A.*

affine and *C. punctatum* is thus supported by the absence of toxicity.

The classification of dinoflagellates is usually based on the combination of morphological and

phylogenetic data of vegetative cells, and accordingly the morphological descriptions of dinoflagellates have usually reflected their phylogenetic relationships. Despite the significant morphological differences between *C. punctatum* and *Alexandrium* species (see next section), it is surprising that the phylogenetic position of *C. punctatum* is nested within the genus *Alexandrium*. The genus *Alexandrium* has been considered as a monophyletic group (Saunders et al. 1997). Under the present circumstances, the phylogenetic placement of *C. punctatum* makes the genus *Alexandrium* non-monophyletic, and an immediate solution is not readily available. A similar situation has arisen for other dinoflagellate genera that encompass many species: *Gymnodinium* s.str. consists not only of *Gymnodinium*-like species but also of polykrikoids and warnowiids (e.g., Hoppenrath et al. 2009), *Gonyaulax* consists of different cyst-based genera (Mertens et al. 2017) and *Protoperidinium* as well (Gu et al. 2015). In addition, Logares et al. (2007) documented that *Scrippsiella hangoei* and *Peridinium aciculiferum*, which have significant morphological and physiological differentiation, can have identical rDNA sequences. Consequently, similar DNA sequences do not always reflect the same morphological characteristics. However, as the molecular data of other *Centrodinium* species have not been determined, further studies are needed to clarify the molecular phylogeny of other *Centrodinium* species.

Possible Morphological Relationship Between *Centrodinium punctatum* and *Alexandrium* species

C. punctatum is clearly distinguished from *Alexandrium* species by its tabulation; the plate tabulation of *C. punctatum* is Po, 3', 1a, 6'', 6C, 8S, 5''', 1p, 2''''', whereas *Alexandrium* species exhibit Po, 4', 6'', 6C, 9–10S, 5''', 2'''' as a plate tabulation (Balech 1995). However, in another Gonyaulacoid, *Protoperidinium reticulatum* (Claparède & Lachmann) Bütschli, the 1a plate is sometimes considered to be an apical plate (e.g., Hansen et al. 1997; Wołoszyńska 1929), suggesting that the 3' plate of *Alexandrium* may be a homologue to the 1a plate of *C. punctatum*. In addition, the sulcal plate arrangement of *C. punctatum* is similar to the *Alexandrium* species (e.g., Balech 1995); the Sa, Sda, Sma and Ssa plates comprise the anterior part of the sulcus and the Sdp, Smp, Ssp and Sp are located on the opposite posterior part.

In the antapical region, the plate tabulation can be considered a fundamental difference between

C. punctatum and *Alexandrium* species. In both genera, there are two antapical plates and one posterior intercalary plate (1p), but the two genera differ in the arrangement and position of these three plates. As the precise homology of these plates should be revealed by study of the overlap in both genera, this is beyond the scope of this study.

Most armored dinoflagellates have a Po that can be distinct feature for generic identification (Hoppenrath 2017). The Po in the apical area of the fusiform species, such as *Centrodinium* and *Spiraulax*, has not been described so far, however based on SEM observations of *C. punctatum*, a small Po composed of a horseshoe-shaped apical pore and many marginal pores is observed, indicating that the Po is similar to the comma-shaped apical pores of *Alexandrium* species described by Balech (1995), MacKenzie et al. (2004) and John et al. (2014). These results are confirmed by the molecular phylogenies of Gonyaulacales; *C. punctatum*, *Alexandrium* and *Pyrodinium* species form a well-supported clade (Fig. S3 in Supporting Information Appendix S1), whereas the genera *Gambierdiscus*, *Gonyaulax*, *Lingulodinium*, *Protoperidinium*, *Tripos* and *Triadinium* that have a slit-like or hook-shaped apical pore are nested within other clades (Dodge and Hermes 1981; Taylor and Fukuyo 1989; Shin et al. 2016). In addition, the Po of *C. punctatum* is quite similar to the Po of the sand-dwelling gonyaulacoid taxa *Thecadinium arenarium* Yoshimatsu, Toriumi & Dodge and *T. yashimaense* Yoshimatsu, Toriumi & Dodge; these species have a horseshoe-shaped apical pore and many marginal pores (Hoppenrath et al. 2004; Yoshimatsu et al. 2004). However, *T. arenarium* and *T. yashimaense* only have one antapical plate, and the cingulum of *Thecadinium* species forms a steep left-handed spiral.

To understand the unexpected phylogenetic position of *C. punctatum* within *Alexandrium* species, the morphological comparisons in the present study are entirely based on morphological features of vegetative cells. Some taxonomic studies revealed that the morphological features of resting stages of dinoflagellates can contribute to the taxonomy and classification of dinoflagellates (e.g., Li et al. 2015; Sarai et al. 2013; Shin et al. 2014). For example, in the genus *Alexandrium*, the resting cyst morphology provides further support for separating species of the *A. tamarensis* species complex and others; they each produce a different type of resting cyst, ellipsoidal or spherical (e.g., Shin et al. 2014). In addition, as the internal morphology, such as dinokaryon, amphiesma and flagellar apparatus, is important for dinoflag-

ellate classification (e.g., [Daugbjerg et al. 2000](#); [Hansen and Moestrup 1998](#)), future studies are needed to examine its ultrastructure and establish the cyst-theca relationship for *C. punctatum* and related species.

Taxonomic Summary

Many species of armored fusiform dinoflagellate species remain poorly known. The present study provided morphological details and molecular data that may allow for characterization of the studied species and to determine its taxonomic position. The present species was closely related to *Alexandrium* species, based on molecular phylogenetic placement. [Taylor \(1976\)](#), [Gómez et al. \(2015\)](#) and other authors have placed *Centrodinium* in the family Oxytoxaceae (Peridinales) and *Alexandrium* in the family Goniodomataceae (Gonyaulacales). As described above, *Centrodinium punctatum* has the following morphological features; the 1' plate is asymmetrical, one posterior intercalary plate, and a horseshoe-shaped apical pore, and the flagellar pore contacts the sulcal anterior plate and the sulcal additional dextral plate touches the cingulum. These morphologies are concordant with the circumscription of the Gonyaulacales given by [Fensome et al. \(1993\)](#). Thus, the genus *Centrodinium* should be placed within the Gonyaulacales rather than the Peridinales. [Kawai and Nakayama \(2015\)](#) revised the taxonomic placement of *Centrodinium* and *Alexandrium* and transferred both genera to the family Heteraulacaceae (Peridinales or Gonyaulacales). However, Heteraulacaceae is considered a synonym of Thoracosphaeraceae and its alternative Goniodomataceae has been rejected; Pyrophacaceae and Ostreopsiaceae are available to replace Goniodomataceae ([Elbrächter and Gottschling 2015](#); [Prud'homme van Reine 2017](#)). Here it is suggested to use Pyrophacaceae to affiliate *Alexandrium* and *Centrodinium* because it has priority over Ostreopsiaceae (it appears earlier in [Lindemann 1928](#) and thus has priority).

***Centrodinium punctatum* (Cleve) F.J.R. Taylor emended Z. Li, K.N. Mertens, E. Nézan, N. Chomérat, M. Iwataki and H.H. Shin**

Emended diagnosis: Armored marine dinoflagellates. Cells solitary, yellow-green in color.

Cells broadly fusiform, not laterally compressed, 40.7–80.6 μm in length, 19.5–40.9 μm in width, 21.4–39.9 μm in depth (dorso-ventral axis), average width-to-depth ratio ~ 1.1 . Cingulum subequatorial, descending, displaced one cingular width. Sulcal lists more developed, slightly deeper than the surrounding plates, located centrally at the apex of the cell. Theca strongly areolated. Plate formula Po, 3', 1a, 6'', 6C, 8S, 5''', 1p, 2'''. Apical pore horseshoe-shaped. Nucleus elongated, sausage-shaped and located centrally on the left side of the cell. Chloroplasts present.

Holotype: Cleve 1900, Plate VIII. [Fig. 4](#).

Basionym: *Steiniella punctata* Cleve 1900 (Kungl. Svenska vetenskapsakademiens handlingar. 34: 18, Plate VIII. [Fig. 4](#).)

Synonyms: *Steiniella punctata* Cleve 1900; *Murrayella punctata* (Cleve) [Kofoid 1907](#); *Pavillardinium punctatum* (Cleve) [de Toni 1936](#); *Murrayella splendida* Rampi 1941; *Pavillardinium splendidum* (Rampi) Rampi 1950 [*vide* [Hernández-Becerril et al. 2010](#)], "*C. mimeticum* (Balech) [Taylor 1976](#)" sensu [Dodge \(1985, p. 114\)](#).

Type Locality: Atlantic Ocean: 48°N, 24°W

Distribution: East China Sea of the Pacific Ocean, offshore Réunion island of the Indian Ocean, and French Atlantic coast.

Authentic Culture Strain: Deposited at the Library of Marine Samples, Korea Institute of Ocean Science and Technology, Geoje 53201, Republic of Korea, under the strain number LIMS-PS-2525.

Methods

Sampling, and isolation and light microscopy of cells collected from East China Sea: Plankton samples were collected during the RV Onnuri cruise in the East China Sea from 16 to 24 August 2016 using a 20 μm -mesh plankton net. Single cells were isolated immediately on the research vessel using a capillary pipette under a light microscope (Eclipse 50i; Nikon, Japan). The isolated cells were inoculated into individual wells of 48-well culture plates (Eppendorf, Germany) filled with sterile F/2 culture medium (Marine Water Enrichment Solution, Sigma-Aldrich, MO, USA) and cultured at room temperature (22 °C) under continuous white light during the sampling periods.

In the laboratory, the cultured cells were transferred to the individual wells of six-well tissue plates by micropipetting. The cells were incubated at 20 °C and ca. 100 $\mu\text{mol photons m}^{-2} \text{s}^{-1}$ cool-white illumination under a 14L:10D photo-cycle. Live cells were isolated from the six-well tissue plates, examined and photographed at $\times 1000$ magnification using an ultra-high resolution digital camera (DS-Ri2; Nikon, Japan) on an upright microscope (ECLIPSE Ni; Nikon,

Japan). After sufficient growth, the cells in the six-well tissue plates were transferred to a culture flask (70025; SPL Life Science, Korea) containing 25 mL sterile F/2 medium. Two culture strains were established successfully, and have been deposited in the Library of Marine Samples, Korea Institute of Ocean Science and Technology, Republic of Korea, as strain numbers LIMS-PS-2525 and LIMS-PS-2526.

For fluorescence microscopy, approximately 1 mL of live, healthy cell culture (LIMS-PS-2525) was transferred to a 1.5-mL microcentrifuge tube, and SYTOX[®] Green Nucleic Acid Stain (Molecular Probes, Eugene, OR, USA) was added at a final concentration of 1.0 μ M. The cells were incubated in the dark at room temperature for 30 min. The cells were observed through a Zeiss Filterset (emission: BP 450–490; beam splitter: FT 510) and photographed using an AxioCam MRc digital camera on an upright microscope (Axio Imager 2; Zeiss, Germany). The Kofoidian system was used to designate the thecal plates (Fensome et al. 1993).

Scanning electron microscopy (SEM) of specimens from East China Sea: For the cultures from East China Sea, 2 mL of mid-exponential batch culture (LIMS-PS-2525) was fixed with 2.0% osmium tetroxide (Sigma-Aldrich) for 15 min at room temperature, then rinsed with sterile-filtered seawater and deionized water. After rinsing, the samples were dehydrated in a graded ethanol series (10–99.9% in eight steps) for 15 min at each step. The samples were then critical point dried using a critical point drying (SPI-Dry Regular Critical Point Dryer, SPI Supplies, West Chester, PA, USA) from liquid CO₂. Finally, the samples were coated with platinum and examined under a JEOL JSM 7600F field emission scanning electron microscope (JEOL Ltd, Tokyo, Japan).

Sampling and isolation for SEM from offshore Réunion Island, Indian Ocean: Plankton samples were collected with a plankton net (20 μ m) on 9 November 2016 from Grande Anse, offshore Réunion Island, Indian Ocean (55.54°E, –21.37°S) and fixed with acidic Lugol's iodine solution (0.1% final concentration) (Andersen and Thronsen 2003).

For SEM, single specimens were isolated from the plankton samples from Réunion Island using a micropipette on a IX70 (Olympus) inverted microscope. The cells were deposited on polycarbonate membrane filters (GTTP Isopore, 0.22 μ m pore size; Millipore, Billerica, MA, USA), which were rinsed with distilled water and stuck to a stub using double-sided adhesive tape. The stubs were air-dried, sputter-coated with gold, and examined using a Sigma 300 Gemini (Carl Zeiss Inc., Oberkochen, Germany) field-emission SEM equipped with both a conventional Everhart-Thornley and in-lens secondary electron detectors at 1.5 kV.

DNA extraction and sequencing of specimens from East China Sea: Genomic DNA was extracted from 1 mL of exponentially growing cultures of strains LIMS-PS-2525 and LIMS-PS-2526 using the DNeasy[®] Plant Mini Kit (QIAGEN Inc., Valencia, CA, USA) following the manufacturer's instructions. The SSU rDNA sequence was amplified using the primer pairs SR1 and SR9, SR4 and SR12b, and DIN464F and EK-1498R (Gómez et al. 2009, 2010; Yamaguchi and Horiguchi 2005). Part of the LSU rDNA sequence was amplified using the primer pairs D1R and R2 (Takano and Horiguchi 2006), and 25F1 and 25R1 (Yamaguchi and Horiguchi 2005). The PCR was conducted using a thermoblock (T100[™] Thermal Cycler; Bio-Rad, USA) at 95 °C for 2 min, followed by 35 cycles of denaturation at 94 °C for 30 s, annealing at 55 °C for 30 s, and extension at 72 °C for 2 min. The reaction was completed with a final elongation at 72 °C for 5 min. The ITS1-5.8S-ITS2 sequence was amplified using the primer pairs ITS1 and ITS4 (White

et al. 1990), ITSFor and ITSRev (Murray et al. 2012). Amplification conditions were 95 °C for 5 min, followed by 35 cycles at 95 °C for 1 min; at 52 °C for 1 min; and at 72 °C for 2 min with a final extension step at 72 °C for 7 min. The sequences of Cox1 and Cob was amplified using the primer pairs Dinocox1F and Dinocox1R, Dinocob1F and Dinocob1R, respectively (Lin et al. 2009). PCR for both Cox1 and Cob was performed using the following program: 95 °C for 1 min, followed by 35 cycles of 20 s at 94 °C, 30 s at 56 °C, and 30 s at 72 °C, and finally an elongation step of 7 min at 72 °C. Hsp90 sequences were amplified using the primer pairs F4 and R2 (Hoppenrath and Leander 2010), and High Fidelity PrimeSTAR[®] GXL DNA Polymerase (TaKaRa Bio Inc., Japan). PCR amplifications consisted of 95 °C for 5 min; 35 cycles of 35 cycles of 10 s at 98 °C, 30 s at 55 °C, and 1 min at 68 °C; and a final extension period at 68 °C for 5 min. For single-cell PCR analysis, a single cell was isolated and transferred to a 200 μ L thin-wall PCR tube (Axygen, Union City, CA, USA). PCR amplification was carried out in a 50- μ L reaction volume with KOD-plus-DNA Polymerase (Toyobo, Osaka, Japan). Primers for amplification of SSU, ITS and partial LSU rDNA were SR1 and R2 for the first round PCR. Takara Ex Taq DNA Polymerase (TaKaRa Bio Inc., Japan) was used for the other rounds of PCR. The SSU, ITS and partial LSU rDNA sequences were amplified using the primer pairs SR1 and SR9, SR4 and SR12b, DIN464F and EK-1498R, ITS-For and ITSRev, and D1R and R2 were also employed. The PCR-amplified products were confirmed by 1% agarose gel electrophoresis. The PCR products were purified using the QIAquick PCR Purification Kit (QIAGEN). The cycle sequencing reaction was performed using the ABI PRISM[®] BigDye[™] Terminator Cycle Sequencing Ready Reaction Kit (Applied Biosystems, USA). The sequences of the strains LIMS-PS-2525 and LIMS-PS-2526 were re-sequenced in the University of Tokyo, Japan.

Single-cell PCR of specimens from French Atlantic coast: For DNA amplification, single cells of *Centrodinium punctatum* were isolated from plankton samples collected with a plankton net (20 μ m) on 9 December 2014 and 6 January 2015 in Concarneau Bay, French Atlantic and fixed with acidic Lugol's iodine solution (0.1% final concentration) under an Olympus IX70 inverted light microscope (Olympus, Tokyo, Japan), and deposited on a glass slide. They were observed at 600 \times magnification, photographed with an Olympus DP72 digital camera (Olympus, Tokyo, Japan), and rinsed with double distilled water (Milli-Q water; Millipore) before transfer to a 0.2 mL PCR tube containing 3 μ L of Milli-Q water. PCR tubes were stored at –20 °C until direct PCR amplifications. For PCR, tubes were thawed and processed as described in Nézan et al. (2012). The nuclear marker SSU rDNA was amplified using the primers 18S-FW and 18S-RV (Chomérat et al. 2010).

Multiple sequence alignments and phylogenetic analysis: Sequences were viewed and assembled in DNABaser version 4.36 (<http://www.dnabaser.com>). Contigs were imported into MEGA version 7.0 (Kumar et al. 2016) and aligned using ClustalW with default settings. Sequence alignments were manually edited using BioEdit version 7.2.5, excluding poorly aligned positions (Hall 1999). The GTR+I+G substitution model was selected using the Akaike information criterion as implemented in jModelTest version 2.1.4 (Darriba et al. 2012). The final alignment of the SSU rDNA dataset consisted of 52 taxa and contained 1617 characters (including gaps inserted for alignment). Two sequences of the unarmored dinoflagellate *Karlodinium veneficum* (D. Ballantine) J. Larsen (GenBank accession numbers JF791046 and JF791048) were used as the outgroup. For the analysis of LSU rDNA sequences, the dataset contained 53 taxa and consisted of 1336 charac-

ters (including gaps inserted for alignment). Sequences of the unarmored dinoflagellate *K. antarcticum* de Salas (GenBank accession number EF469234) and *K. decipiens* de Salas & Laza-Martinez (EF469236) were used as the outgroup. For the analysis of ITS1-5.8S-ITS2 sequences, the dataset contained 44 taxa and consisted of 663 characters (including gaps inserted for alignment). Sequences of the unarmored dinoflagellate *K. australe* de Salas, Bolch & Hallegraeff (KJ670420) and *K. veneficum* (AF352367) were used as the outgroup. The separate alignments were then checked and concatenated using SequenceMatrix version 1.8 (Vaidya et al. 2011). The alignment of the concatenated dataset consisted of 29 taxa and 3,724 bp for SSU/ITS/LSU (including gaps inserted for alignment). The sequence of the unarmored dinoflagellate *Gymnodinium aureolum* (Hulburt) G. Hansen (DQ779991) was used as the outgroup. The final alignment of the concatenated dataset consisted of 34 taxa and 7,394 bp for SSU/ITS/LSU/Cox1/Cob/Hsp90 (including gaps inserted for alignment). Sequences of perkinsozoans were used as outgroup.

Phylogenetic trees derived from each dataset were constructed using maximum likelihood (ML) and Bayesian inference analyses. The ML analyses were performed using PhyML version 3.1 (Guindon et al. 2010). The starting tree was generated using BIONJ with optimization of the topology, branch lengths, and selected rate parameters. Six different substitution rates were selected. Bootstrap analyses of both datasets were carried out for ML with 1000 replicates to assess statistical reliability. Bayesian inference analyses were conducted on five datasets using MrBayes version 3.2 (Ronquist et al. 2012). The evolutionary model used in Bayesian inference analyses were the GTR+I+G model with gamma-distributed rate variation across sites. Five Markov chain Monte Carlo (MCMC) chains were run for 10 million generations, sampling every 100 generations.

Acknowledgements

This work was supported by grants from the Marine Biotechnology Program of the Korea Institute of Marine Science and Technology Promotion (KIMST) funded by the Ministry of Oceans and Fisheries (MOF) (No. 20170431), and Korea Institute of Ocean Science and Technology (KIOST) project (PE99721). We thank Alina Tunin-Ley (Hydrô Réunion) for sampling offshore waters on Réunion Island. The Regional Council of Brittany, the General Council of Finistère and the urban community of Concarneau-Cornouaille-Agglomération are acknowledged for the funding of the Sigma 300 FE-SEM of the station of Marine Biology in Concarneau. Malte Elbrächter is acknowledged for taxonomic advice.
