ABSTRACT

Half-sandwich organometallic complexes of curcumin are extensively investigated as anticancer compounds. Speciation studies were performed to explore the solution stability of curcumin complexes formed with $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$. Acetylacetonone (Hacac), as the simplest β -diketone ligand bearing (O,O) donor set, was involved for comparison and its $\text{Ru}(\eta^6\text{-p-cymene})$, $\text{Ru}(\eta^6\text{-toluene})$ complexes were also studied. ^1H NMR, UV-visible and pH-potentiometric titrations revealed a clear trend of stability constants of the acac complexes: $\text{Ru}(\eta^6\text{-p-cymene}) > \text{Ru}(\eta^6\text{-toluene}) > \text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$. Despite this order, the highest extent of complex formation is seen for the $\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$ complexes at pH 7.4. Formation constant of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ reveals similar solution stability to that of the acac complex. Additionally, structures of two complexes were determined by X-ray crystallography. The *in vitro* cytotoxicity of curcumin was not improved by the complexation with these organometallic cations.

1. Introduction

The field of anticancer drug research is governed by two main factors: efficacy and selectivity. *Cisplatin* (cis-diammine-dichloridoplatinum(II)) and its derivatives are the leading compounds of the metal-based chemotherapeutics [1,2]. They possess high cytotoxicity, although their use is limited by acquired resistance and side effects caused by the low selectivity [1]. The development of novel compounds based on platinum group metal ions is an attractive alternative. The Ru(III)-containing *trans*-[tetrachlorido(DMSO)(imidazole) ruthenate(III)] (*NAMI-A*) [3] and *trans*-[tetrachloridobis(1*H*-indazole)ruthenate(III)] (*KP1339/IT-139*) are considered as the most promising candidates, and the latter complex already demonstrated remarkable anticancer activity in a phase I clinical trial [4,5]. Ru(III) is assumed to be activated by reduction giving the impetus for the development of Ru(II) compounds. A novel Ru(II) compound, [ruthenium(II)(4,4'-dimethyl-2,2'-bipyridine)2-(2-(2',2'':5'',2''':terthiophene)-imidazo[4,5-*f*] [1,10] phenanthroline)] Cl_2 (*TLD-1433*, *NCT03053635*) has entered clinical trials in 2016 as a photodynamic agent [6]. In the half-sandwich arrangement Ru(II) is protected from hydrolysis and oxidation by the coordination of an aromatic ligand, and faster ligand-exchange processes can be

observed [7,8]. The assumed mechanism of action of this type of complexes is often connected to their ability to bind to biomolecules and/or to their redox properties. $[\text{Ru}(\eta^6\text{-arene})(\text{PTA})\text{Cl}_2]$ (RAPTA) complexes (where PTA = 1,3,5-triaza-7-phosphaadamantane) show *in vivo* activity combined with low toxicity [9]. The group of $[\text{Ru}(\eta^6\text{-arene})(1,2\text{-ethylenediamine})\text{Cl}]^+$ (RAED) compounds developed by Sadler et al. also exhibits significant anticancer activity [10,11].

The congener Os(II), Rh(III) and Ir(III) compounds are paid somewhat less attention, although some of their half-sandwich complexes have as high cytotoxicity as cisplatin [7,12]. The physico-chemical properties of the $[\text{Ru}/\text{Os}(\eta^6\text{-arene})(\text{X},\text{Y})(\text{Z})]$ and $[\text{Rh}/\text{Ir}(\eta^5\text{-arenyl})(\text{X},\text{Y})(\text{Z})]$ complexes can be optimized by changing the building blocks, e.g. the arene (or arenyl) ring, the bidentate (X,Y) ligand or the co-ligand (Z).

Compounds bearing (O,O) donor set are often used as ligands like cyclobutane dicarboxylate in carboplatin, or oxalate in oxaliplatin [1]. These ligands are found in carbo-RAPTA and oxali-RAPTA as well [9]. β -Diketones are one of the oldest groups of (O,O) ligands used in analytical and synthetic approaches and a plenty of their half-sandwich complexes were synthesized [13]. The simplest β -diketone molecule is acetylacetonone (Hacac, Chart 1), however there are numerous natural

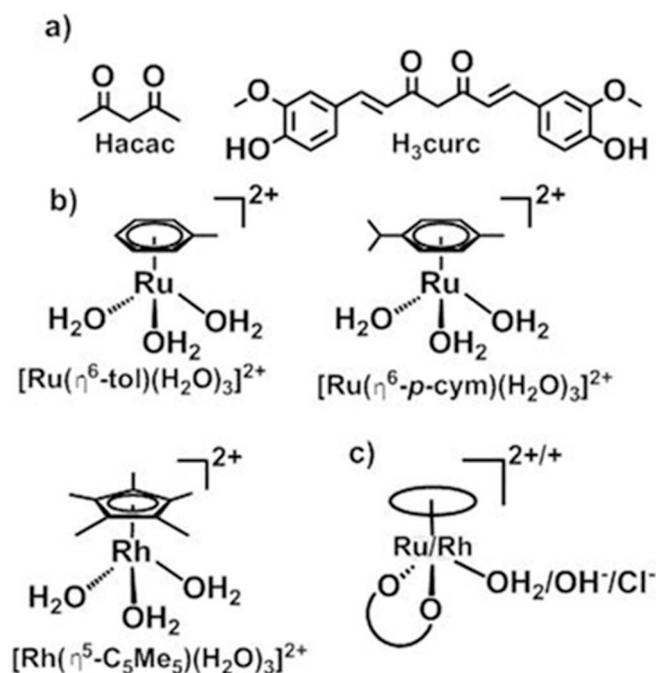

Chart 1. a) Chemical structures of the investigated (O,O) bidentate ligands: acetylacetone (Hacac) and curcumin (H₃curc); and b) organometallic half-sandwich triaquacations. c) General chemical structure of the mono complexes formed with (O,O) bidentate ligands.

compounds containing this motif such as dibenzoylmethane (*Glycyrrhiza glabra*) [14], gingerols (*Zingiber officinale*) or curcumin (*Curcuma longa*) [15,16]. The most attractive property of them is their low toxicity against healthy cells and they possess intrinsic anticancer properties [15,16].

Curcumin (H₃curc, Chart 1) and its derivatives alone or in combination with metal ions have been reported to show significant antitumor activity and induce paraptotic effects on cancer cells [17]. Curcumin is able to overcome P-glycoprotein mediated multidrug resistance in human cancer cells *via* the inhibition of this transporter [15,16]. However curcumin has very low solubility in water, it is photosensitive and may completely hydrolyse under strongly basic conditions [18–20]. These features make the solution equilibrium studies fairly difficult.

The insufficient pharmacokinetic properties of curcumin can be overcome by binding to a protein or a metal ion [19–21]. A plethora of curcumin metal complexes was synthesized in which the ligand could be stabilized. These complexes are potential photosensitizers for photodynamic therapy in cancer treatment [21]. Its half-sandwich Ru(II) complex was tested against human cancer cell lines showing moderate activity (*IC*₅₀ = 13.98–62.33 μM) [22]. The [Rh(η⁵-C₅Me₅)(H₂curc)(H₂O)]⁺ complex is considered as a delivery system of curcumin since its cytotoxicity is similar to that of the ligand itself [23]. The combination of PTA and curcumin in half-sandwich organo-metallic complexes could enhance the bioactivity [13].

Despite the high number of organometallic complexes formed with curcumin and its derivatives reported in the literature, the solution stability of this type of compounds was not characterized and compared to analogous species. As the metal complexes are generally considered as prodrugs and can undergo ligand exchange processes in biofluids, information about their solution speciation is needed for understanding of their transformation processes. Therefore solution stability, aquation (replacement of the chlorido leaving group by a water molecule) and deprotonation processes were already studied in our former works in case of half-sandwich complexes containing (pentamethylcyclopentadienyl)rhodium(III) (Rh(η⁵-C₅Me₅)), (*p*-cymene)ruthenium(II) (Ru(η⁶-

p-cym)) and (toluene)ruthenium(II) (Ru(η⁶-tol)) as the organometallic fragment and various bidentate ligands [24–29]. Herein our aim was to investigate the complex formation of curcumin (H₃curc) and acetylacetone (Hacac) with [Rh(η⁵-C₅Me₅)(H₂O)₃]²⁺, [Ru(η⁶-*p*-cym)(H₂O)₃]²⁺ and [Ru(η⁶-tol)(H₂O)₃]²⁺ organometallic cations (Chart 1) using pH-potentiometry, UV–visible (UV–Vis) and ¹H NMR spectroscopy. Interaction of the acac complexes with human serum albumin (HSA) and cell culture medium components was characterized by spectrofluorometry and ¹H NMR spectroscopy to reveal the possible transformation processes. Effect of the complexation on the *in vitro* cytotoxicity of curcumin was also tested in multidrug resistant Colo 320/MDR-LRP human colonic adenocarcinoma cell lines.

2. Results and discussion

2.1. Hydrolysis of the organometallic cations and proton dissociation processes of ligands

For the complete description of the equilibrium processes in the organometallic cation – ligand systems the hydrolysis constants of the metal ions and the proton dissociation constants of the ligands are needed. The hydrolytic behaviour of the organometallic [Ru(η⁶-*p*-cym)(H₂O)₃]²⁺ and [Ru(η⁶-tol)(H₂O)₃]²⁺ cations has been already studied by Buglyó et al. in the presence and in the absence of chloride ions [30]. The fast hydrolysis of the aquated organoruthenium cations yields the species [(Ru(η⁶-arene))₂(μ²-OH)₃]⁺ that becomes predominant at pH > ~4.5 (tol) and ~5 (*p*-cym). When 0.2 M KCl was used as the background electrolyte, like in our studies, formation of various chlorido and mixed chlorido/hydroxido species as intermediates was found in addition to the major hydrolysis product [(Ru(η⁶-arene))₂(μ²-OH)₃]⁺ [31].

Stability constants for the hydrolysis products of [Rh(η⁵-C₅Me₅)(H₂O)₃]²⁺ have been reported by our group, namely for [(Rh(η⁵-C₅Me₅))₂(μ²-OH)₂(H₂O)₂]²⁺ and [(Rh(η⁵-C₅Me₅))₂(μ²-OH)₃]⁺ dinuclear species [24]. The hydrolysis of Rh(η⁵-C₅Me₅)(H₂O)₃]²⁺ starts at higher pH compared with the Ru(η⁶-arene) species. It is worth to note that the chloride ions are coordinating ligands in case of the studied half-sandwich organometallic complexes; thus the possible partial displacement of aqua ligands by chlorides should be considered and the determined stability constants are conditional constants obtained at the given chloride concentration.

Proton dissociation process of acetylacetone (Hacac) is well-known in the literature and the p*K*_a constant determined by pH-potentiometry in this work (Table 1) is in a good agreement with the reported values [32]. Acetylacetone has two tautomeric forms, namely keto and enol, which are distinguishable in the ¹H NMR spectra due to the slow exchange processes on the NMR time-scale (Fig. S1). The reported enol/keto equilibrium constant is log *K*_{enol/keto} = 0.21 [32], and a similar constant was determined based on our measurements (log *K*_{enol/keto} = 0.23 ± 0.02). As a consequence the keto form predominates in aqueous solutions in the whole pH range studied.

Curcumin has the same β-diketonato group as Hacac, although the proton dissociation occurs not merely in this moiety since the two phenolic hydroxyl groups have dissociable protons as well. Only few data can be found for the p*K*_a values of these moieties in the literature most probably as a consequence of the low water solubility and light-induced decomposition of this compound [33,34]. Therefore, the proton dissociation constants of curcumin were determined by UV–Vis spectroscopy in a 95% water/5% ethanol mixture using low concentration (5 μM) and individual samples kept in dark (see Fig. S2). By the deconvolution of the recorded UV–Vis spectra three p*K*_a values were calculated (Table 1). Presumably the β-diketonato group has the lowest p*K*_a, which is actually lower than the same group's constant in the Hacac molecule. The two higher constants belong to the overlapping deprotonation of the two 2-methoxyphenolic groups.

Table 1

Proton dissociation constants (pK_a of the studied ligands and stability constants ($\log K$ [ML]) of organometallic acetylacetonate complexes and overall stability constant ($\log \beta$ [MLH₂]) of [Rh(η^5 -C₅Me₅)(H₂curc)(H₂O)]⁺, pK_a [ML], pH_{max} , %_{ML,max} and $pM^*_{7.4}$ values determined by various methods, and H₂O/Cl⁻ exchange constants ($\log K'$ [ML]) for [Rh(η^5 -C₅Me₅)(acac)(H₂O/Cl)]^{+ / 0} { $T = 25$ °C; $I = 0.2$ M (KCl)}.^a

^a The overall stability constants of organometallic cation's hydrolysis products: $\log \beta$ [(Ru(η^6 -tol))₂(μ^2 -OH)₂]²⁺ = -6.50, $\log \beta$ [(Ru(η^6 -tol))₂(μ^2 -OH)₃]⁺ = -10.56; $\log \beta$ [(Ru(η^6 -p-cym))₂(μ^2 -OH)₂]²⁺ = -7.12, $\log \beta$ [(Ru(η^6 -p-cym))₂(μ^2 -OH)₃]⁺ = -11.88; $\log \beta$ [(Rh(η^5 -C₅Me₅))₂(μ^2 -OH)₂]²⁺ = -11.12, $\log \beta$ [(Rh(η^5 -C₅Me₅))₂(μ^2 -OH)₃]⁺ = -19.01 at $I = 0.2$ M (KCl) taken from Refs. [24, 30].

^b Taken from Ref. [35].

^c Determined by pH-potentiometric titrations.

^d Determined by UV-Vis titrations at pH = 6.0–11.6.

^e Determined by ¹H NMR titrations.

^f Constant for [Rh(η^5 -C₅Me₅)(H₂curc)(H₂O)]⁺ determined by UV-Vis spectrometry at pH = 6.8, $c(M)/c(L) = 0.0$ –8.6.

^g Calculated for systems containing $c(M) = c(L) = 5$ μ M. pH_{max} is the pH at which the extent of the formation of the metal complexes is the highest and %_{ML,max} is the highest fraction of ML under this condition. $pM^* = -\log([M]^{2+} + 2[M_2(\mu^2-OH)_2]^{2+} + 2[M_2(\mu^2-OH)_3]^+)$.

^h Calculated for systems containing $c(M) = c(L) = 5$ μ M and at pH = 7.4.

ⁱ Determined by UV-Vis spectrometry: $c(Cl^-) = 0.0$ –0.3 M, pH = 7.3.

2.2. Complex formation equilibria of acac with [Rh(η^5 -C₅Me₅)(H₂O)₃]²⁺ and [Ru(η^6 -tol)(H₂O)₃]²⁺

As studies on the solution speciation of curcumin complexes are limited owing to the insufficient water solubility and light-sensitivity, acetylacetonate, possessing a similar coordination mode, served as a water soluble model ligand. The solution speciation of the [Ru(η^6 -p-cym)(H₂O)₃]²⁺ – acac system was already studied by Bíró et al., and they determined the $\log K$ [ML] formation constant for the mono complex ($\log K$ [ML] = 8.56, $I = 0.2$ M KCl) [35]. (M denotes the organometallic triaqua cation in which the aqua ligand is partly replaced by the chlorido ligands and the donor atoms of the ligands.) Fernández et al. determined the pK_a [ML] constant (9.41) for the deprotonation of the coordinated water, although a chloride-free medium was applied ($I = 0.1$ M NaClO₄) [36].

Stability constants of acetylacetonate complexes formed with the other two organometallic cations were determined by the combined use of pH-potentiometric and ¹H NMR titrations in the presence of 0.2 M chloride ions. It is worth mentioning that complex formation was found to be fairly fast in all cases. In the speciation model formation of mono complexes such as [ML] and [ML(OH)] was used based on single crystal X-ray diffraction results (*vide infra*) and the findings on analogous complexes of other bidentate (O,O) ligands investigated previously [24,25,35]. Fig. 1 shows ¹H NMR spectra recorded for the [Rh(η^5 -C₅Me₅)(H₂O)₃]²⁺ – acac system in the pH range from 1.9 to 11.4. At acidic pH range (pH < 3.5) only the peaks of the free organometallic ion and free ligand (in both the keto and enol forms) can be identified. In the pH range 3.5–10.0 a new set of signals appears which is related to the formation of complex [Rh(η^5 -C₅Me₅)(L)(H₂O)]⁺ that predominates at physiological pH (in which H₂O is partly replaced by Cl⁻).

On the other hand in case of the [Ru(η^6 -tol)(H₂O)₃]²⁺ – acac system, formation of mixed hydroxido complex [Ru(η^6 -tol)(acac)(OH)] can be also detected at pH > 8 (Fig. S3,a). The aqua and hydroxido complexes are in equilibrium with high exchange rates that cannot be resolved in the NMR time scale. Thus the peaks of the mono complex are high-field shifted as the pH is increased and draw a sigmoid curve (Fig. S3,c). This phenomenon allows the determination of pK_a [ML]

constant from the change of the chemical shifts (Table 1). As the signals assigned to free and bound acac ligand as well as to the unbound and bound organometallic fragments appear separately in the ¹H NMR spectra the integrated peak areas could be converted to molar fractions. Based on the molar fractions at the different pH values stability constants ($\log K$ [ML]) were computed for the [Ru(η^6 -tol)(H₂O)₃]²⁺ – acac and [Rh(η^5 -C₅Me₅)(H₂O)₃]²⁺ – acac systems (Table 1). They are in a fairly good agreement with data determined by pH-potentiometry. In order to compare the stability constants of acac complexes to those of other simple (O,O) donor ligands, $\log K$ [ML] and pK_a [ML] values were determined for deferiprone (1,2-dimethyl-3-hydroxy-pyrid-4(1H)-one) and maltol (3-hydroxy-2-methyl-pyran-4(1H)-one) (Chart S1) complexes of Ru(η^6 -tol) by pH-potentiometry. (Constants were already reported for deferiprone and maltol complexes of Rh(η^5 -C₅Me₅) and Ru(η^6 -cym) [24,25,35].) The $\log K$ [ML] for the deferiprone Ru(η^6 -tol) complex is 11.74 ± 0.08 and pK_a [ML] is 9.34 ± 0.09, while only one constant was determined in the [Ru(η^6 -tol)(H₂O)₃]²⁺ – maltol system ($\log K$ [ML] = 8.97 ± 0.01). The trend of the $\log K$ [ML] constants of the acac species is the following: [Ru(η^6 -p-cym)(acac)(H₂O)]⁺ > [Ru(η^6 -tol)(acac)(H₂O)]⁺ >> [Rh(η^5 -C₅Me₅)(acac)(H₂O)]⁺, which is the same trend as seen with other (O,O) donor ligands such as maltol [24,35] and deferiprone [25,35]. To compare the apparent solution stability of the acac complexes pM^* values were computed and plotted against the pH (Fig. 2). pM^* value, which is defined as the negative logarithm of the equilibrium concentrations of the unbound metal ion (in all forms: triaqua cation and μ -hydroxido dinuclear species) under the given conditions (pH, total concentrations of the ligand and metal ion). Notably, pM was introduced by Raymond et al. [37] to compare the relative affinities of ligands towards a given metal ion. Therefore, a higher pM^* value reflects the stronger metal binding ability of the ligand. Due to the stronger tendency of [Ru(η^6 -arene)(H₂O)₃]²⁺ cations to undergo hydrolysis at physiological pH compared to that of [Rh(η^5 -C₅Me₅)(H₂O)₃]²⁺ [24,30], the highest extent of complex formation is found in the [Rh(η^5 -C₅Me₅)(H₂O)₃]²⁺ – acac system under the same conditions (Fig. 2). Table 1 also contains the % [ML] at these pH values and the $pM^*_{7.4}$ values.

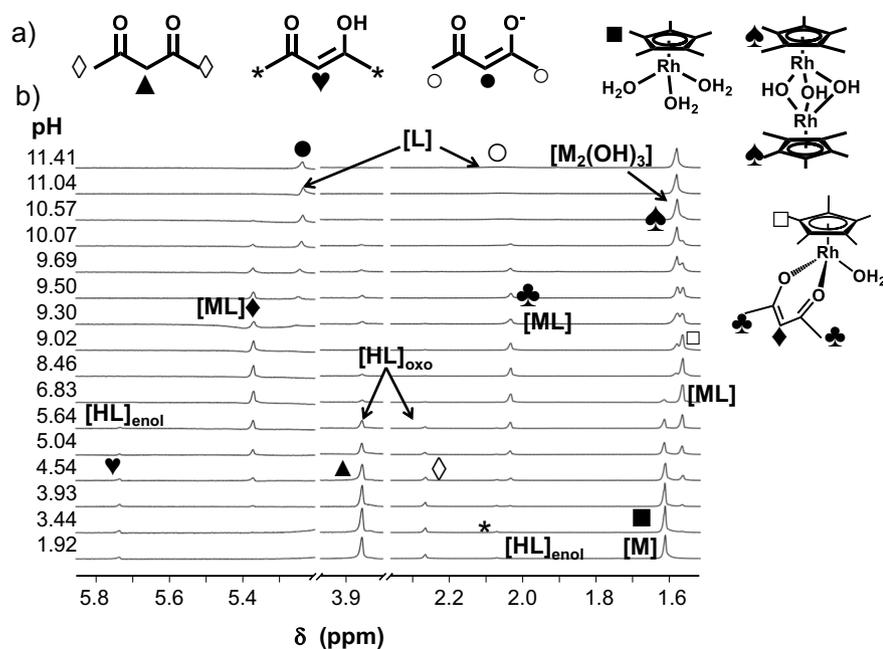

Fig. 1. a) Chemical structures of compounds present in the $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ - acac system. b) ^1H NMR spectra of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ - acac system recorded at pH = 1.9–11.4. Peak assignment is shown on the structures of a). (M denotes the organometallic half-sandwich triaquacation. Notably the aqua ligand is partly displaced by chloride, see Section 2.1) $\{c(\text{acac}) = 2.0 \text{ mM}; c([\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}) = 2.1 \text{ mM}; \text{solvent: } 90\% \text{ H}_2\text{O} / 10\% \text{ D}_2\text{O}; T = 25.0 \text{ }^\circ\text{C}; I = 0.2 \text{ M (KCl)}\}$.

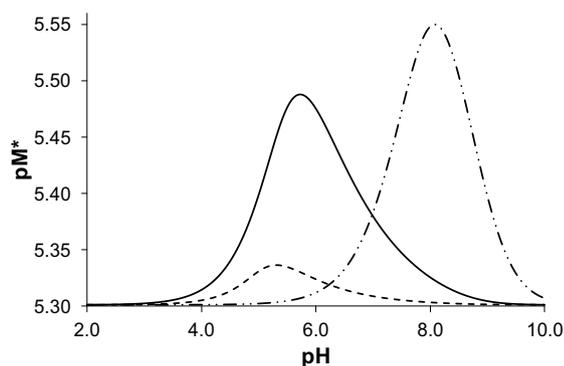

Fig. 2. Calculated pM^* -curves obtained for the organometallic cation - acac systems plotted against the pH. $\text{M} = [\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ (---); $[\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{O})_3]^{2+}$ (—) [35]; $[\text{Ru}(\eta^6\text{-tol})(\text{H}_2\text{O})_3]^{2+}$ (- - -). $\{c(\text{acac}) = c(\text{M}) = 5 \text{ } \mu\text{M}; T = 25.0 \text{ }^\circ\text{C}; I = 0.2 \text{ M (KCl)}\}$.

2.3. Complex formation equilibrium of curcumin with $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$

Concentrations necessary for pH-potentiometric and ^1H NMR titrations cannot be reached in pure water in case of curcumin. As curcumin has very intense colour, UV-Vis spectrophotometric titrations were performed in 95% water/5% ethanol mixture. Stock solution was prepared before the measurements by dissolving curcumin in ethanol and then storing in the dark. In ethanol the hydrolysis of curcumin does not occur [18]. In case of $[\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{O})_3]^{2+}$ and $[\text{Ru}(\eta^6\text{-tol})(\text{H}_2\text{O})_3]^{2+}$ the spectral changes showed that their curcumin complexes have even lower solubility than curcumin itself leading to precipitation. Therefore, stability constants for the $\text{Ru}(\eta^6\text{-arene})$ complexes could not be obtained under these conditions. In order to determine the stability constant for the $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{H}_2\text{O})]^+$ complex known amounts of the organometallic cation were added to the ligand and UV-Vis spectra were recorded while the pH was kept constant (pH 6.8) using phosphate buffer (Fig. S4.). During the titration the organorhodium cation was added to curcumin at a maximum of 9-fold excess. Formation of a $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{H}_2\text{O})]^+$ complex is assumed as the deprotonation of the non-coordinating 2-methoxyphenolic groups

under these conditions is not probable based on the pK_a values of curcumin. Since the determination of the stability constants of the organoruthenium complexes of curcumin failed, it is an interesting point to check how good binding model is acac for curcumin. The stability constants determined for the complexes of acac and curcumin cannot be compared directly due to the different deprotonation processes of the ligands. Thus, concentration distribution curves for the $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ - acac and $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ - curcumin systems are represented in Fig. 3. It can be concluded that the curves run rather close to each other for both systems, however the curcumin complex shows a slightly higher stability. Therefore, acac is not a perfect but an adequate binding model ligand for the solution speciation studies of curcumin complexes.

The solution stability of the studied half-sandwich $\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$ complexes of acac and curcumin was compared to that of (O,O) donor bearing ligands such as maltol [24], allomaltol (5-hydroxy-2-methyl-4H-pyran-4-one, Chart S1) [24] or deferiprone [25] via the calculation of pM^* values at various pH values (Fig. 4). It can be concluded that curcumin and acac form complexes with lower stability than the other ligands with 5-membered chelate ring.

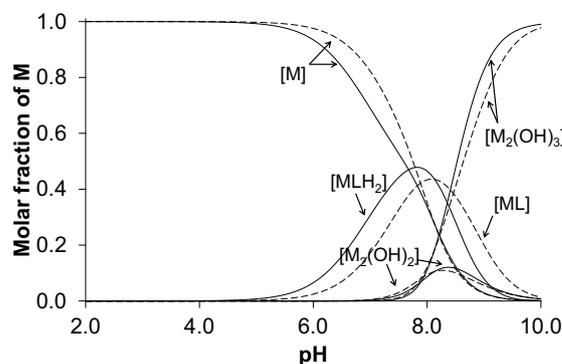

Fig. 3. Calculated concentration distribution curves of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ - acac (dashed lines) and $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ - curcumin (solid lines) systems based on the stability constants from Table 1. $\{c(\text{M}) = c(\text{acac}) = c(\text{curcumin}) = 5 \text{ } \mu\text{M}; T = 25.0 \text{ }^\circ\text{C}; I = 0.2 \text{ M (KCl)}\}$.

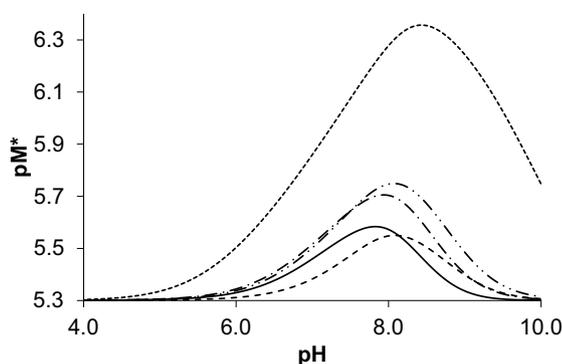

Fig. 4. Calculated pM^* -curves of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ – (O,O) bidentate ligand systems plotted against the pH. Notations for the various ligands: acac (---); curcumin (—); allomaltol [24] (-.-.-); maltol [24] (-.-.-); deferiprone [25] (—). $pM^* = -\log([M] + 2[M_2(\text{OH})_3] + 2[M_2(\text{OH})_2])$, where M denotes the triaqua organometallic cation. Notably the coordinated H_2O is partly replaced by Cl^- in the complexes in the presence of the chloride ions, see Section 2.1. $\{c(\text{M}) = c(\text{L}) = 5 \mu\text{M}; T = 25.0^\circ\text{C}; I = 0.2 \text{ M (KCl)}\}$.

2.4. Structural studies on organometallic Rh(III) and Ru(II) complexes

Single crystals were obtained for metal complexes $\text{Ru}(\eta^6\text{-tol})(\text{acac})\text{Cl}$ (**1**) and $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}] \times 2\text{MeOH}$ (**2**) by the reaction of the ligands deprotonated by sodium methoxide and the corresponding organometallic dimer precursors. The dimeric ruthenium precursor $[\text{Ru}(\eta^6\text{-tol})(\mu^2\text{-Cl})\text{Cl}]_2$ was prepared according to literature procedures by the reaction of $\text{RuCl}_3 \times 3\text{H}_2\text{O}$ with 1-methyl-1,4-cyclohexadiene [38], while $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\mu^2\text{-Cl})\text{Cl}]_2$ is commercially available. The mixtures of the ligands and the precursors were refluxed for 4 h and then the solvent was removed. The complex was dissolved and extracted with CH_2Cl_2 . Single crystals of the acac complex were grown in concentrated methanolic solutions. In the case of the $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{Cl})]$ complex crystals were obtained from a mixture of $\text{MeOH}/\text{CH}_2\text{Cl}_2$.

The $[\text{Ru}(\eta^6\text{-tol})(\text{acac})(\text{Cl})]$ complex was crystallized without any remaining solvent molecule, while $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{Cl})]$ crystallized with two methanol molecules in the asymmetric unit. The ORTEP representation of the complexes showing the atom and ring labels is depicted in Fig. 5. The complexes crystallized in the monoclinic and in the orthorhombic crystal system, in space group $P2_1/c$ and $Pbcn$, respectively. Selected bond distances and angles are collected in Table 2, structure refinement and crystal data are shown in Table S1. The geometry of the complexes are pseudo-tetrahedral: they show the

so-called three-legged ‘piano-stool’ geometry similarly to the previously determined complexes with bidentate (O,O) and Cl^- donor groups [22,24,25,36,39]. Additional information about hydrogen bonds and packing arrangements in crystal **1** is collected in Table S2 and Figs. S5 and S6.

The curcumin molecule is coordinated *via* its deprotonated acac oxygens (O1 and O2) forming a six-membered chelate ring with the Rh(III) ion. The metal–O distances and bite angles in these complexes are close to the values found in the analogous $[\text{Ru}(\eta^6\text{-p-cym})(\text{acac})(\text{Cl})]$ (2.074 Å, 88.0 $^\circ$) [36] and $[\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{curc})(\text{Cl})]$ [22] (2.071 Å, 87.4 $^\circ$) structures. These data show that acac is a good structural model of curcumin. On the other hand, the replacement of the arene moiety from *p*-cymene to toluene does not result in measurable effect on bond lengths and angles. The distance between the centre of gravity of the C_5Me_5 ring (ring A) and the Rh centre is 1.7485(15) Å, which falls within the range obtained for relevant Rh complexes (1.730–1.759 Å) [24,25,39–45]. In the complex with the heavier congener iridium ($[\text{Ir}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{Cl})]$) this distance is found to be 1.753 Å and the bite angle is 87.5 $^\circ$, which is slightly different. However, the metal–O distance is 2.100 Å, which is longer than in the Rh and Ru complexes [45].

The two phenolic oxygens O3 and O5 remained protonated in $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}]$. The curcumin molecule has a slightly bent conformation. The methoxy groups of the two 4-hydroxy-3-methoxyphenyl rings (ring C and D) are turned in opposite positions and the angle between the plane of the two rings is 15.32(15) $^\circ$. The molecule is not symmetrically bended, ring B and C are almost in plane (the angle between their planes is 3.95(16) $^\circ$), while higher angle could be measured between the planes of rings B and D (11.52(15) $^\circ$). On Fig. S7 different views of packing arrangement in crystal **2** are

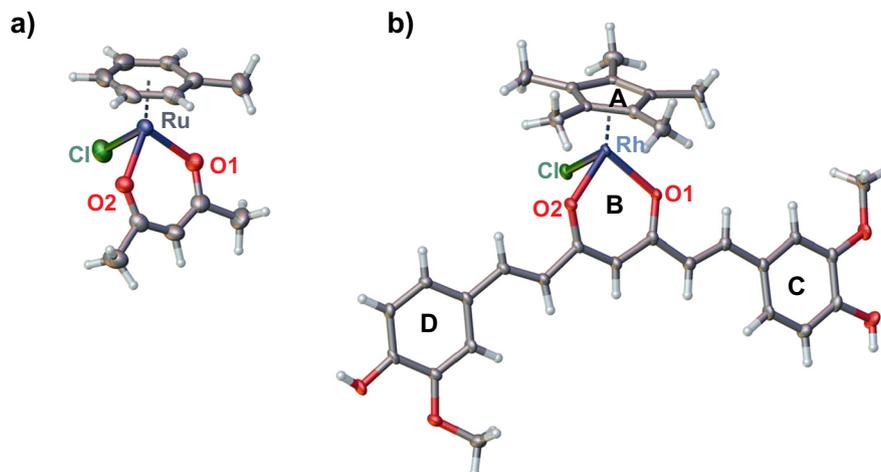

Fig. 5. a) Molecular structures of $[\text{Ru}(\eta^6\text{-tol})(\text{acac})\text{Cl}]$ (**1**) and b) $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}] \times 2\text{MeOH}$ (**2**) with labels on rings. Displacement parameters are drawn at 50% probability level; solvent molecules are omitted for clarity.

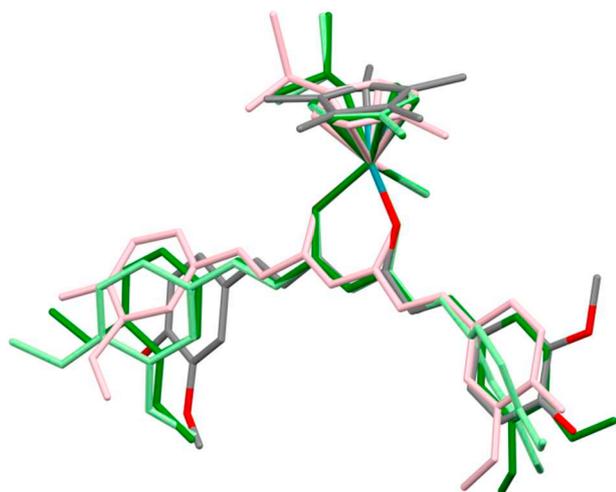

Fig. 6. Comparison of molecular structure of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{Cl})]$ (**2**) (coloured by element) with $[\text{Ru}(\eta^6\text{-cym})(\text{H}_2\text{curc})(\text{Cl})]$ (pink) (Ref. code GESYAG) [22] and the two molecules in the asymmetrical unit of $[\text{Ru}(\eta^6\text{-cym})(\text{dimethylH}_2\text{curc})(\text{Cl})]$ (dark and light green) (Ref. code RESXUI) [46]. Ru/Rh ions with the two oxygen and the chlorido ligands are superimposed.

shown. Fig. S8 shows the crystal-stabilizing hydrogen bond system and intermolecular distances are collected in Table S3.

Though the analogous Ru(II)-chlorido complex of curcumin was already crystallized [22], this is the first structure with its Rh(III) analogue. Fig. 6 shows the comparison in the molecular conformations in crystal **2** with those of $[\text{Ru}(\eta^6\text{-cym})(\text{H}_2\text{curc})(\text{Cl})] \times \text{H}_2\text{O}$ (Ref. code GESYAG) [22] and $[\text{Ru}(\eta^6\text{-cym})(\text{dimethylH}_2\text{curc})(\text{Cl})] \times \text{CHCl}_3 \times \text{H}_2\text{O}$ (Ref. code RESXUI) [46] where two molecules are in the asymmetric unit. It is clearly seen that the curcumin molecules can adopt very different conformations and bending of the rings C and D can be even higher than in crystal **2** (see Table 3).

2.5. $\text{H}_2\text{O}/\text{Cl}^-$ exchange in $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$

In the crystal structures of the studied half-sandwich organometallic complexes the coordination sphere of Ru(II) and Rh(III) contains the arene or arenyl group, the (O,O) donor bidentate and a chlorido ligand. While dissolving the complex in water, the good leaving group Cl^- can be substituted by a water molecule. It is considered as an important activation step according to the mechanism of action of similar complexes [47], since the chlorido complex is suggested to be less reactive and charge neutral. Notably, the chloride ion concentration changes in biofluids: in the blood serum it is 100 mM, 23 mM in the cytoplasm and 4 mM in the nucleus [47]. The ratio of the aqua and chlorido complexes is changing as the compound reaches the nucleus from blood and this ratio is governed by the rate of the exchange process and $\log K'$ ($\text{H}_2\text{O}/\text{Cl}^-$) constant.

Based on the ^1H NMR spectra, in the case of $\text{Ru}(\eta^6\text{-p-cymene})$ and $\text{Ru}(\eta^6\text{-toluene})$ there is no pH range where only the acac complex is

Table 3

Comparison of the angles between curcumin ring planes in crystals $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{Cl})]$, $[\text{Ru}(\eta^6\text{-cym})(\text{H}_2\text{curc})(\text{Cl})]$ [22] and $[\text{Ru}(\eta^6\text{-cym})(\text{dimethylH}_2\text{curc})(\text{Cl})]$ [46].

Coloured	$[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{Cl})]$	$[\text{Ru}(\eta^6\text{-cym})(\text{H}_2\text{curc})(\text{Cl})]$	$[\text{Ru}(\eta^6\text{-cym})(\text{dimethylH}_2\text{curc})(\text{Cl})]$	
	By element	Pink	Dark green	Light green
AB (°)	67.8	51.7	66.0	69.2
BC (°)	4.0	8.1	11.8	47.5
BD (°)	11.5	13.2	14.7	38.5

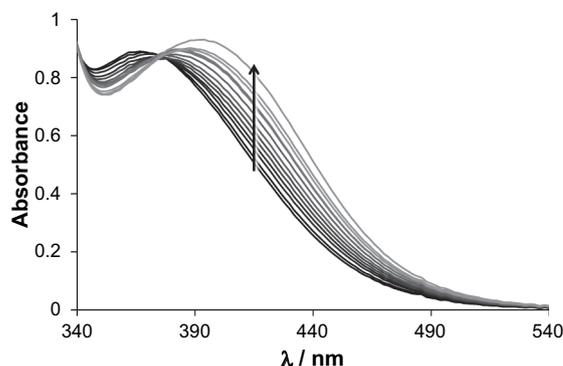

Fig. 7. UV-Vis absorption spectra of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$ in the presence of chloride ions at different concentrations. $\{c([\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}) = c(\text{acac}) = 1 \text{ mM}; c(\text{Cl}^-) = 0\text{--}300 \text{ mM}; \text{pH} = 7.30$ (phosphate buffer); $T = 25.0 \text{ }^\circ\text{C}\}$.

present in solution at 2 mM concentration. Therefore, this constant was determined only for the $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$ complex at $\text{pH} = 7.30$ spectrophotometrically, using the same approach as in our previous works [24–29]. The water/chloride exchange was found to be fast, equilibrium could be reached within few minutes. In Fig. 7 the spectral changes are clearly seen as the chloride ion concentration is increasing and the presence of one isobestic point proves the equilibrium between two species.

The $\log K'$ ($\text{H}_2\text{O}/\text{Cl}^-$) constant is determined as 1.11 ± 0.03 (for fitting of the absorbance values see Fig. S9), that reflects a moderate chloride ion affinity of the complex. Comparing this value to those of similar (O,O) donor bearing ligands' complexes e.g. maltol (1.17) [24], allomaltol (1.38) [24], deferiprone (0.78) [25], they are quite similar to each other, which means a relatively weak chloride ion affinity. Based on this constant it can be predicted that 56%, 23% and 5% are the fractions of the chlorido species at 1 mM concentration of the complex and at physiological pH in blood serum, cytoplasm and nucleus, respectively.

2.6. *In vitro* cytotoxicity and interaction with proteins

Curcumin and its complexes were tested as anticancer compounds in a human colonic adenocarcinoma cell line Colo 320/MDR-LRP multidrug resistant overexpressing ABCB1 (MDR1)-LRP, using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) method. Literature data reveal that $[\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{curc})\text{Cl}]$ showed moderate cytotoxicity on HCT116 colon adenocarcinoma cell line ($IC_{50} = 13.98 \text{ } \mu\text{M}$) [22]. $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}]$ possesses a similar activity as curcumin itself on A549 lung adenocarcinoma cells and the complex seems to be a delivery system of curcumin [23]. Herein the *in vitro* cytotoxicity studies of curcumin in the absence and in the presence of the various organometallic cations were carried out and IC_{50} values (after 24 and 72 h incubation) are collected in Table 4.

Data reveal that curcumin and its premixed $\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$ complex have similar cytotoxic effect, while for the premixed organoruthenium complexes lower bioactivity was determined. Based on these values the free curcumin is effective alone, while complexation with $[\text{Rh}(\eta^5\text{-$

Table 4

In vitro cytotoxicity (IC_{50} values in μM in Colo 320 human colon cancer cell lines) of curcumin and its complexes.

	IC_{50} (μM) (24 h)	IC_{50} (μM) (72 h)
Curcumin + $\text{Ru}(\eta^6\text{-tol})(\text{H}_2\text{O})_3]^{2+}$	82.3 ± 1.5	20.46 ± 3.73
Curcumin + $\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{O})_3]^{2+}$	63.1 ± 3.6	26.06 ± 1.58
Curcumin + $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$	34.8 ± 0.2	11.94 ± 0.99
Curcumin	39.6 ± 2.4	14.73 ± 1.1

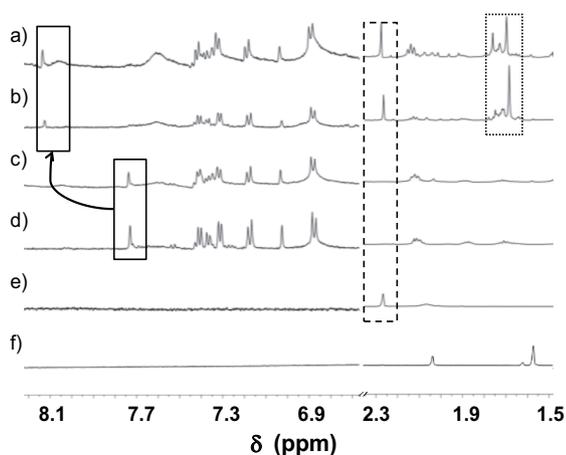

Fig. 8. ^1H NMR spectra recorded for $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$ in RPMI 1640 and RPMI 1640 with 10% FBS media. a) $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$ in RPMI 1640 with 10% FBS medium; b) $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$ in RPMI 1640 medium; c) RPMI 1640 with 10% FBS medium; d) RPMI 1640 medium; e) free acac in buffered solution at pH = 7.4 (PBS'); f) $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$ in buffered solution at pH = 7.4 (PBS'). Dotted rectangle: C_5Me_5 protons at various binding environment; dashed rectangle: free acac methyl groups; solid rectangles: His proton. $\{c([\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+) = c(\text{acac}) = 1 \text{ mM}$; solvent: 90% H_2O / 10% D_2O ; $T = 25.0^\circ\text{C}$; $t = 24 \text{ h}$.

$\text{C}_5\text{Me}_5(\text{H}_2\text{O})_3]^{2+}$ does not disturb this effect, although complex formation with $[\text{Ru}(\eta^6\text{-p-cymene})(\text{H}_2\text{O})_3]^{2+}$ and $[\text{Ru}(\eta^6\text{-toluene})(\text{H}_2\text{O})_3]^{2+}$ interferes with it. To understand better the findings of the *in vitro* cytotoxic measurements the effect of the cell culture medium components on complex stability was studied. Cancer cells were grown in Roswell Park Memorial Institute (RPMI) 1640 medium supplemented with 10% heat-inactivated fetal bovine serum (FBS) and 10 mM HEPES. This modified medium contains different inorganic salts, amino acids and some other small biomolecules, e.g. folic acid and choline chloride from RPMI 1640 and various serum proteins from FBS. The serum components have effects on stability of both curcumin and its complex, since the hydrolytic stability of curcumin is increasing [19,20], however the coordination of amino acid side chains can cause decomposition of the original metal complex [28]. Interaction of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$ and RPMI 1640 components with and without FBS was monitored by ^1H NMR spectroscopy (Fig. 8).

The chloride ion content of this medium is $\sim 110 \text{ mM}$, which means that around 56% of the complex is chlorinated on the basis of the determined $\log K'(\text{H}_2\text{O}/\text{Cl}^-)$ constant. The recorded ^1H NMR spectra show that the complex dissociates in both media: free acac is detected and the organometallic rhodium cation is in different environments, most probably His is bound to it. In the FBS modified medium different peaks are seen which indicate protein-rhodium interactions. In the case of the organoruthenium cations complex decomposition can be detected, but there is no difference in the binding environment in the two types of medium (Figs. S10 and S11).

Human serum albumin (HSA) is the main transport protein in blood and considered as an useful model protein to examine the protein – metal complex interactions. It can bind drug molecules in its binding pockets non-specifically and metal ions and complexes through coordinating side chains. Using spectrofluorimetry binding close to binding site I (IIA subdomain) can be monitored, as Trp-214 is sensitive to the binding in this pocket and it can be selectively excited. The binding of curcumin to HSA was already investigated several times by other groups and with different methods [48,49]. The binding constant is determined as $\log K = 5.79$ by spectrofluorimetry and one curcumin molecule binds to one HSA molecule [50].

Binding of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ and $[\text{Ru}(\eta^6\text{-tol})(\text{H}_2\text{O})_3]^{2+}$ towards HSA was characterized previously in our research group [28,29].

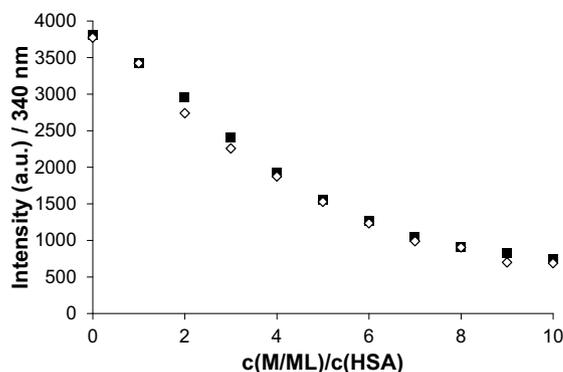

Fig. 9. Fluorescence emission intensity at 340 nm of the HSA – $[\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{O})_3]^{2+}$ (\diamond) and the HSA – $[\text{Ru}(\eta^6\text{-p-cym})(\text{acac})(\text{H}_2\text{O})]^+$ (\blacksquare) systems. $\{\lambda_{\text{EX}} = 295 \text{ nm}$; $c(\text{HSA}) = 1 \mu\text{M}$; $c([\text{Ru}(\eta^6\text{-tol})(\text{H}_2\text{O})_3]^{2+}) = c(\text{acac}) = 0\text{--}10 \mu\text{M}$; $T = 25.0^\circ\text{C}$; $\text{pH} = 7.4$ (PBS' buffer); $t = 24 \text{ h}$.

The interaction of HSA and $[\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{O})_3]^{2+}$ has the same characteristics as in the two other cases. Quenching constant ($\log K'_Q$) can be calculated based on the emission changes of Trp-214. In the case of $[\text{Ru}(\eta^6\text{-p-cym})(\text{H}_2\text{O})_3]^{2+}$ this value is 5.60 ± 0.01 . HSA has high metal ion affinity, because it can bind at least 8-fold excess of these cations [28,29]. Based on spectrofluorimetric and ultrafiltration experiments the binding of acac to HSA was excluded.

In our experimental setup $1 \mu\text{M}$ of HSA was titrated with the organometallic ions and with their acac complexes from 1:1 up to 1:10 HSA-to-metal ion/or complex ratio and emission spectra were recorded upon excitation at 295 nm after 24 h waiting time. Fig. 9 shows the spectral changes as the function of HSA-to-metal ion/complex ratio in case of the $\text{Ru}(\eta^6\text{-p-cym})$ species as representative example. The presence of acac results in negligible difference.

Then ultrafiltration/UV-Vis measurements were performed to reveal in which form the acac complexes bind to the protein. We found that free acac appears in the filtrate (see Fig. S12.) with only a very small amount of complex. Therefore, most of the organometallic ions are bound to the protein and the ligand is cleaved, so they exhibit a dissociative binding mode.

3. Conclusions

Curcumin and organometallic half-sandwich complexes are the focus of attention since their anticancer activity is widely reported. The half-sandwich curcumin complexes are very attractive drug candidates but limited data are reported about their stability in aqueous solution and in biological media. In this work we determined the pK_a values of curcumin and stability constants of the curcumin complex of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ with UV-Vis spectroscopy in aqueous solution and in dark. It was found that acetylacetone is not a perfect but still a good binding model for curcumin based on the determined stability constants, since $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{H}_2\text{O})]^+$ shows only slightly higher stability than $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{acac})(\text{H}_2\text{O})]^+$. These complexes possess lower stability than other half-sandwich Rh and Ru complexes formed with (O,O) bidentate ligands. The trend of the stability constant ($\log K [\text{ML}]$) values determined is $\text{Ru}(\eta^6\text{-p-cymene}) > \text{Ru}(\eta^6\text{-toluene}) > \text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$. However, due to the highest hydrolytic stability of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ cation, at physiological pH the $\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$ complex is formed at the highest extent. In the basic pH range, decomposition of metal complexes to $[\text{M}_2(\text{OH})_3]^+$ is observed and formation of the mixed hydroxido complex $[\text{Ru}(\eta^6\text{-tol})(\text{acac})(\text{OH})]$ is detected. The water/chlorido exchange constant provides information about the ratio of aqua and chlorido complexes in different biological media at physiological pH. 56%, 23% and 5% were found to be the ratio of the chlorido complex in blood serum, cytoplasm and nucleus, respectively at 1 mM concentration of the $\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)\text{-acac}$ complex.

The *in vitro* cytotoxicity tests in a multidrug resistant human colonic adenocarcinoma cell line revealed that only the complex $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})(\text{H}_2\text{O})]^+$ shows similar anticancer activity compared to that of curcumin, the $[\text{Ru}(\eta^6\text{-arene})(\text{H}_2\text{O})_3]^{2+}$ cations decrease this effect. It was also found that the interaction of these complexes with cell culture medium components and serum proteins results in decomposition of complexes. ^1H NMR spectra indicate that the organometallic fragment is bound to amino acids and proteins. Upon the interaction with the model protein HSA decomposition of metal complexes and metal binding *via* the release of the ligand was detected.

4. Experimental

4.1. Chemicals

All solvents were of analytical grade and used without further purification. $[\text{Ru}(\eta^5\text{-C}_5\text{Me}_5)(\mu^2\text{-Cl})\text{Cl}]_2$, $[\text{Ru}(\eta^6\text{-p-cym})(\mu^2\text{-Cl})\text{Cl}]_2$, curcumin ($\geq 99.5\%$), acetylacetone, maltol, deferiprone, $\text{RuCl}_3 \times 3\text{H}_2\text{O}$, KCl, AgNO_3 , HCl, KOH, 4,4-dimethyl-4-silapentane-1-sulfonic acid (DSS), HSA (as lyophilized powder with fatty acids, A1653), RPMI 1640, NaH_2PO_4 , Na_2HPO_4 , KH_2PO_4 , toluene, ethanol and methanol were purchased from Sigma-Aldrich in puriss quality. Doubly distilled Milli-Q water was used for sample preparation. The dimeric ruthenium precursor $[\text{Ru}(\text{II})(\eta^6\text{-tol})(\mu^2\text{-Cl})\text{Cl}]_2$ was prepared according to literature procedures [38] (see Supplementary Information). The exact concentration of the ligand stock solutions together with the proton dissociation constants were determined by pH-potentiometric titrations with the use of the computer program HYPERQUAD [51]. The aqueous $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3](\text{NO}_3)_2$ stock solution was obtained by dissolving an exact amount of the dimeric precursor in water followed by the removal of chloride ions by addition of equivalent amounts of AgNO_3 . The exact concentrations of chloride ion containing and chloride free metal ion stock solutions were determined by pH-potentiometric titrations employing stability constants for $[(\text{Rh}(\eta^5\text{-C}_5\text{Me}_5))_2(\mu^2\text{-OH})_i]^{(4-i)+}$, $[(\text{Ru}(\eta^6\text{-tol}))_2(\mu^2\text{-OH})_i]^{(4-i)+}$ and $[(\text{Ru}(\eta^6\text{-p-cym}))_2(\mu^2\text{-OH})_i]^{(4-i)+}$ ($i = 2$ or 3) complexes [24,30].

The stock solution of curcumin was prepared prior to the analysis on a weight-in-volume basis dissolved in ethanol and kept in dark. HSA solution was freshly prepared before the experiments and its concentration was estimated from its UV absorption: $\epsilon_{280\text{nm}}(\text{HSA}) = 36,850 \text{ M}^{-1} \text{ cm}^{-1}$ [52]. It was dissolved in a modified phosphate buffered saline (PBS') at pH 7.40. PBS' contains 12 mM Na_2HPO_4 , 3 mM KH_2PO_4 , 1.5 mM KCl and 100.5 mM NaCl; and the concentration of the K^+ , Na^+ and Cl^- ions corresponds to that of the human blood serum.

4.2. Synthesis of the complexes $[\text{Ru}(\eta^6\text{-tol})(\text{acac})\text{Cl}]$ and $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}]$

$[\text{Ru}(\eta^6\text{-tol})(\text{acac})\text{Cl}]$ and $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}]$ were prepared according the literature procedure used for the analogous $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\beta\text{-diketonato})\text{Cl}]$ complexes [45] by adding the dimeric precursor (0.1 mmol, 0.050 g for the Ru-dimer and 0.058 g for the Rh-dimer) to the dichloromethane and methanol solution mixture (10 mL and 3 mL respectively) of the ligand (0.025 mL for acetylacetone and 0.090 g for curcumin (0.25 mmol)) and NaOCH_3 (0.013 g, 0.25 mmol). This mixture was refluxed for 4 h. The solvent was evaporated *in vacuo* and the metal complex was extracted with CH_2Cl_2 . Single crystals suitable for X-ray crystallographic analysis were grown from methanol ($[\text{Ru}(\eta^6\text{-tol})(\text{acac})\text{Cl}]$) and methanol/ CH_2Cl_2 mixture ($[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}]$). HRMS (m/z): found: 293.0111 (calculated for $\text{RuC}_{12}\text{H}_{15}\text{O}_2$ $[\text{Ru}(\eta^6\text{-tol})(\text{acac})]^+$ ($[\text{ML}]^+$): 293.0116; found: 605.1398 (calculated for $\text{RhC}_{31}\text{H}_{34}\text{O}_6$ $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{-H}]^+$ ($[\text{ML-H}]^+$): 605.1411).

ESI-MS measurements were performed using a Micromass Q-TOF Premier (Waters MS Technologies) mass spectrometer equipped with electrospray ion source.

4.3. Crystallographic structure determination

Single crystals suitable for X-ray diffraction experiment of compounds $[\text{Ru}(\eta^6\text{-tol})(\text{acac})\text{Cl}]$ (1), and $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{curc})\text{Cl}] \times 2\text{MeOH}$ (2) were grown from MeOH or $\text{CH}_2\text{Cl}_2/\text{MeOH}$ solution resulting in yellow and red single crystals, respectively. They were mounted on a loop and transferred to the goniometer. X-ray diffraction data were collected at -170°C on a Rigaku RAXIS-RAPID II diffractometer using $\text{Mo-K}\alpha$ radiation for crystal 1 and $\text{Cu-K}\alpha$ for crystal 2. A numerical absorption correction [53] was carried out in case of crystal 1 and a multi-scan absorption correction was used in case of crystal 2 using the software CrystalClear [54]. Sir2014 [55] and SHELXL [56] under WinGX [57] softwares were used for structure solution and refinement, respectively. The structures were solved by direct methods. The models were refined by full-matrix least squares on F^2 . Refinement of non-hydrogen atoms was carried out with anisotropic temperature factors. Hydrogen atoms were placed into geometric positions. They were included in structure factor calculations but they were not refined. The isotropic displacement parameters of the hydrogen atoms were approximated from the $U(\text{eq})$ value of the atom they were bonded to. The summary of data collection and refinement parameters are collected in Table S1. Selected bond lengths and angles of compounds were calculated by PLATON software [58]. The graphical representation and the edition of CIF files were done by Mercury [59] and PubCif [60] softwares, respectively. The crystallographic data files for the complexes have been deposited with the Cambridge Crystallographic Database as CCDC 1882689 and 1882690.

4.4. pH-Potentiometric measurements

pH-Potentiometric measurements determining proton dissociation constants of ligands and overall stability constants for the metal complexes were carried out at $25.0 \pm 0.1^\circ\text{C}$ in water and at a constant ionic strength of 0.20 M KCl. The titrations were performed in a carbonate-free KOH solution (0.20 M). The exact concentrations of HCl and KOH solutions were determined by pH-potentiometric titrations. An Orion 710A pH-meter equipped with a Metrohm combined electrode (type 6.0234.100) and a Metrohm 665 Dosimat burette were used for the pH-potentiometric measurements. The electrode system was calibrated to the $\text{pH} = -\log[\text{H}^+]$ scale by means of blank titrations (HCl vs. KOH), as suggested by Irving et al. [61]. The average water ionization constant, pK_w , was determined as 13.76 ± 0.01 at 25.0°C , $I = 0.20 \text{ M}$ (KCl), which is in accordance to literature [62]. The reproducibility of the titration points included in the calculations was within 0.005 pH units. The pH-potentiometric titrations were performed in the pH range between 2.0 and 11.5. The initial volume of the samples was 5.0 mL. The ligand concentration was 2.0 mM and was investigated at metal ion-to-ligand ratios of 1:1, 1:1.5, and 1:2. The accepted fitting between the measured and calculated titration data points regarding the volume of the titrant was $< 10 \mu\text{L}$. Samples were degassed by bubbling purified argon through them for about 10 min prior to the measurements and the inert gas was also passed over the solutions during the titrations.

The computer program PSEQUAD [63] was utilized to establish the stoichiometry of the complexes and to calculate the overall stability constants. $\beta(\text{M}_p\text{L}_q\text{H}_r)$ is defined for the general equilibrium:

where M denotes the metal moiety $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ or $[\text{Ru}(\eta^6\text{-arene})(\text{H}_2\text{O})_3]^{2+}$ and L the completely deprotonated ligand. β

values for the various hydroxido complexes $[(\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)_2(\mu^2\text{-OH}))_i]^{(4-i)+}$, $[(\text{Ru}(\eta^6\text{-tol}))_2(\mu^2\text{-OH}))_i]^{(4-i)+}$ and $[(\text{Ru}(\eta^6\text{-}p\text{-cym}))_2(\mu^2\text{-OH}))_i]^{(4-i)+}$ ($i = 2$ or 3) were calculated based on the pH-potentiometric titration data and were found to be in good agreement with the previously published data [24,30].

4.5. UV–Vis spectrophotometric and ^1H NMR measurements

A Hewlett Packard 8452A diode array spectrophotometer was used to record the UV–Vis spectra in the interval 200–800 nm. The path length (l) was 0.5, 1, or 2 cm. The proton dissociation constants of curcumin were determined spectrophotometrically by batch method to avoid the photodegradation. Samples contained 5 μM curcumin and 5% (v/v) ethanol. UV–Vis spectra were used to investigate the $\text{H}_2\text{O}/\text{Cl}^-$ exchange processes of complexes at 1 mM concentration, at pH 7.30 (20 mM phosphate buffer) as a function of chloride concentrations (0–300 mM).

^1H NMR studies were carried out on a Bruker Avance III HD 500 MHz instrument. All ^1H NMR spectra were recorded with the WATERGATE water suppression pulse scheme using DSS internal standard. Acetylacetonate was dissolved in a 10% (v/v) $\text{D}_2\text{O}/\text{H}_2\text{O}$ mixture to yield a concentration of 2 mM and was titrated at 25 °C, at $I = 0.20\text{ M}$ (KCl) in absence or presence of $[\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)(\text{H}_2\text{O})_3]^{2+}$ and $[\text{Ru}(\eta^6\text{-tol})(\text{H}_2\text{O})_3]^{2+}$ at 1:1 metal-to-ligand ratio. Stability constants for the complexes were calculated by the computer program PSEQUAD [63].

4.6. Fluorescence and membrane ultrafiltration/UV–Vis studies with HSA

Fluorescence spectra were recorded on a Hitachi-F4500 fluorimeter in 1 cm quartz cell at 25.0 ± 0.1 °C. All solutions were prepared in PBS' (pH 7.40) and were incubated for 15 min or 24 h. Samples contained 1 μM HSA and various HSA-to-ligand or metal ion or metal complex ratios (from 1:0 to 1:10) were used. The excitation wavelength was 295 nm and the emission was read in the range of 305–450 nm. The quenching constant ($\log K'_q$) was calculated with the computer program PSEQUAD [63] using the same approach applied in our previous works [28,29].

Samples were separated by ultrafiltration through 10 kDa membrane filters (Microcon YM-10 centrifugal filter unit, Millipore) in low (LMM) and high molecular mass (HMM) fractions with the help of a temperature controlled centrifuge (Sanyo, 10,000/s, 10 min). Samples (0.50 mL) contained 50 μM HSA and $\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$ or its acac complex (150 μM) in PBS' buffer (pH 7.30) at 25.0 ± 0.1 °C and were incubated for 24 h. The LMM fraction containing the non-bound metal complex was separated from the protein and its adducts in the HMM fraction. The concentration of the non-bound compounds in the LMM fractions was determined by UV–Vis spectrophotometry by comparing the recorded spectra to those of reference samples without the protein. When the complex decomposed due to the protein binding, free ligand was also detected in the LMM fraction. In this case the recorded spectra were deconvoluted using the molar absorbance spectra of the ligand and metal complex by Excel Solver (Microsoft Office 2007).

4.7. Cell lines, culture conditions and cytotoxicity tests in cancer cell lines

Cell lines and culture conditions: All cell culture reagents were obtained from Sigma-Aldrich and plastic ware from Sarstedt (Germany). Human colonic adenocarcinoma cell line Colo 320/MDR-LRP multidrug resistant overexpressing ABCB1 (MDR1)-LRP (ATCC-CCL-220.1) was purchased from LGC Promochem, Teddington, UK. The cells were cultured in RPMI 1640 medium supplemented with 10% heat-inactivated fetal bovine serum, 2 mM L-glutamine, 1 mM sodium pyruvate and 10 mM 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES). The cells were incubated at 37 °C, in a 5% CO_2 , 95% air atmosphere. The semi-adherent human colon cancer cells were

detached with Trypsin-Versene (EDTA) solution for 5 min at 37 °C.

MTT assay: Curcumin and its premixed $\text{Rh}(\eta^5\text{-C}_5\text{Me}_5)$ and $\text{Ru}(\eta^6\text{-arene})$ complexes were dissolved in an ethanol/PBS' (1:1) mixture first, diluted in complete culture medium, then two-fold serial dilutions of compounds were prepared in 100 μL of RPMI 1640, horizontally. The semi-adherent colonic adenocarcinoma cells were treated with Trypsin-Versene (EDTA) solution. They were adjusted to a density of 1×10^4 cells in 100 μL of RPMI 1640 medium, and were added to each well, with the exception of the medium control wells. The final volume of the wells containing compounds and cells was 200 μL .

The culture plates were incubated at 37 °C for 24 or 72 h; at the end of the incubation period, 20 μL of MTT (Sigma) solution (from a stock solution of 5 mg/mL) were added to each well. After incubation at 37 °C for 4 h, 100 μL of sodium dodecyl sulfate (SDS) (Sigma) solution (10% in 0.01 M HCl) were added to each well and the plates were further incubated at 37 °C overnight. Cell growth was determined by measuring the optical density (OD) at 540/630 nm with Multiscan EX ELISA reader (Thermo Labsystems, Cheshire, WA, USA). Inhibition of the cell growth (IC_{50}) was determined according to the formula below:

$$100 - \left[\frac{\text{OD}_{\text{sample}} - \text{OD}_{\text{medium control}}}{\text{OD}_{\text{cell control}} - \text{OD}_{\text{medium control}}} \right] \times 100$$
