## ABSTRACT

A highly efficient catalytic system based on Pd(OAc)<sub>2</sub> and an imidazole-hydrazone ligand has been developed for Suzuki–Miyaura cross-coupling reaction in water under aerobic conditions using IR-irradiation. The system can tolerate a wide range of functionalized arylboronic acids and aryl halides. Furthermore, this protocol is also applicable for hetero-aryl bromides.

## 1. Introduction

The palladium catalyzed Suzuki–Miyaura reaction between organoboron compounds and organic halides is one of the most powerful and convenient approaches for forming C–C and C–X (X = O, N), particularly for the synthesis of biaryls, amides and esters [1]. Owing to the fact that the aryl–aryl structure motif is an important building block in organic chemistry, the Suzuki–Miyaura reaction is widely applied in academic research as well as in industrial synthesis of fine chemicals and highly complex pharmaceuticals [2].

This popularity of the reaction results from the broad functional group tolerance, the commercial availability and low toxicity of the organoborons, the mild reaction conditions, ease of handling of products and by-products, and the possibility of using water as a solvent or co-solvent [3,4].

The Suzuki–Miyaura cross-coupling reaction is usually catalyzed by a wide variety of Pd-based catalysts and the effectiveness

of the catalytic system is dependent on the ligand environment around palladium. In traditional Suzuki–Miyaura reactions, the electron-rich phosphine ligands were generally employed to improve the catalytic performance [5]. Since phosphine ligands are often water- and air-sensitive [6], catalysis under phosphine-free conditions is still a challenge of high importance. Different nitrogen based ligands such as *N*-heterocyclic carbenes [7], palladacycle species [8], *N,O*- or *N,N*-bidentate ligands [9], aryloximes [10], *O*-aryloxime ethers [11], arylimines [12], *N*-acylamidines [13], amines [14], 2-aryl-2-oxazolines [15], and arylhydrazones [16] have emerged as efficient ligands for Suzuki–Miyaura reactions with the potential to overcome most of the drawbacks of traditional phosphine ligands.

Additionally, the classic Suzuki–Miyaura reaction was often carried out in organic media, such as DMF [17], THF [18], dioxane [19], toluene [20], CH<sub>3</sub>CN [21], or methanol, [22]. Recently, this coupling reaction has strongly benefited from aqueous media [23], most of substrates used are insoluble in water but numerous efforts have been made, such as synthesizing water-soluble ligands [24], adding surfactants and/or phase-transfer agents [25], or using microwave [26] or ultrasound [27]. Yet, most aqueous protocols for

cross coupling reactions have some drawbacks such as high catalyst loading [24b,25d,28], long reaction times [29], or require the addition of organic co-solvents [30], including ligand-free protocols [25d,28,30b]. From these standpoints, the development of an efficient, stable, economical, and environmentally friendly catalytic system remains a challenging task.

On the other hand, new alternative heating methodologies such as microwave [31], ultrasound [32], and infrared (IR) irradiation [33] have been applied in organic synthesis and catalysis with reduced reaction times, cleaner reaction mixtures and good yields. As a research program focused on the use of IR irradiation in C-C coupling reactions, recently we explored the use of IR irradiation to assist the Mizoroki-Heck [34,35] and Suzuki-Miyaura [36,37] cross-coupling reactions; in addition, we demonstrated an air stable phosphine-free hydrazone containing a heterocycle moiety as an effective ligand for palladium catalyzed Mizoroki-Heck [35,37] and Suzuki-Miyaura [37] cross couplings under IR irradiation.

However, there are no reports of arylhydrazones containing a heterocycle moiety as ligands for the Suzuki-Miyaura reaction in water using IR irradiation as the energy source. Herein, we report the synthesis of arylhydrazone derivatives containing the imidazole moiety as an effective ligand for palladium-catalyzed Suzuki-Miyaura cross-coupling reactions in water using IR irradiation. This represent an efficient, convenient, and environmentally friendly protocol for this powerful cross-coupling reaction.

## 2. Experimental

### 2.1. Apparatus, materials, and measurements

All operations were carried out in open atmosphere. Column chromatography was performed using 70–230 mesh silica gel. All reagents and solvents were obtained from commercial suppliers and used without further purification. All compounds were characterized by IR spectra, recorded with a Perkin-Elmer 283B or 1420 spectrophotometer, by means of thin film and KBr techniques, and all data are expressed in wavenumbers ( $\text{cm}^{-1}$ ). Melting points were obtained on a Melt-Temp II apparatus and are uncorrected. NMR spectra were measured with a Varian Eclipse 300 using  $\text{CDCl}_3$  as solvent. Chemical shifts are in ppm ( $\delta$ ), relative to TMS. The MS-EI spectra were obtained on a JEOL SX 102a and the MS-DART spectra were obtained with a AccuTOF JMS-T100LC; the values of the signals are expressed in mass/charge units ( $m/z$ ), followed by the relative intensity with reference to a 100% base peak.

The equipment used for irradiation with IR energy was created by employing an empty cylindrical metal vessel in which an Osram lamp (bulb model Thera-Therm, 250 W, 125 V) was inserted [34].

### 2.2. General synthetic procedure for the compounds L1-L3

A solution of the corresponding phenylhydrazine (1.8 mmol) in methanol (5 mL) was added dropwise to a magnetically stirred solution of 1-methyl-2-imidazolecarboxaldehyde (1.8 mmol) in methanol (5 mL). The reaction mixture was refluxed using IR irradiation for 1.5 h to give a yellow solid, which was recovered by filtration and recrystallized from methanol.

### 2.3. General procedure for Suzuki-Miyaura coupling reactions

Inside a 50-mL round-bottom flask, a mixture of aryl halide (0.5 mmol), phenylboronic acid (0.6 mmol), and base (1 mmol) was placed in 3 mL of solvent; then the Pd source and corresponding arylhydrazone **1** were added. The reaction was irradiated with IR energy [34–37] for the time reported in Tables 1 and 2. Thereafter, the reaction was cooled at room temperature; the mixture was diluted with 10 mL of water and extracted with hexane or AcOEt (3 × 10 mL). The combined organic layers were dried over anhydrous sodium sulfate. The crude product was finally purified by column chromatography on silica gel to give the isolated products.

The purified product was identified by means of mp determination and by <sup>1</sup>H and <sup>13</sup>C NMR; the data obtained are consistent with the literature [38].

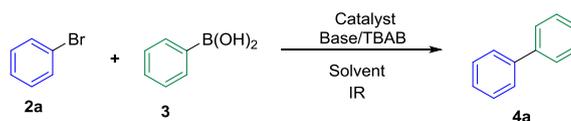

## 3. Results and discussion

### 3.1. Synthesis and characterization of hydrazones L1-L3

The arylhydrazone ligands **L1–L3** were prepared employing the condensation reaction of the corresponding arylhydrazine and 1-methyl-2-imidazolecarboxaldehyde in 1:1 mol ratio in reflux of methanol for 3 h (Scheme 1). After crystallization from methanol the ligand **L1–L3** was obtained as a solid in 98, 92 and 90% yields, respectively, and were fully characterized by conventional spectroscopic methods: <sup>1</sup>H NMR, <sup>13</sup>C NMR, IR and MS.

The infrared spectra of **L1–L3** show an absorption band in a range between 1585 and 1588  $\text{cm}^{-1}$ , which was assigned to the vibration of the C=N bond, that indicated the arylhydrazone formation. The NMR and mass spectra of compounds **L1–L3** were found to be in agreement with their molecular structures. The singlet signals of the <sup>1</sup>H NMR spectra at 7.31 ppm, 7.50 ppm and 7.73 ppm for **L1–L3** respectively; are characteristic of the imine hydrogen. The corresponding imine signals in the <sup>13</sup>C NMR spectrum are found at 129.0 ppm for **L1**, 127.3 ppm for **L2**, and 129.4 ppm for **L3**. Additionally, the structures are supported by mass spectra, the DART mass spectra show the base peak at [M + H]<sup>+</sup> for the molecular cation at  $m/z = 276$  and  $m/z = 214$  for **L1** and **L2** respectively; finally, EI-mass spectrum of **L3** show a molecular

### 3.2. Suzuki-Miyaura cross-coupling reaction

Having synthesized ligands **L1-L3**, we tested the reaction of phenylboronic acid with bromobenzene in 3 mL aqueous media ( $V_{\text{water}}/V_{\text{methanol}}$ , 1/1) as a model reaction at 75 °C using  $\text{K}_3\text{PO}_4$  as base and **L1** as ligand in the presence of  $\text{Pd}(\text{OAc})_2$  and TBAB as additive, under IR irradiation. We found that with catalyst loads of 1 mol % and 0.5 mol % [ $\text{Pd}(\text{OAc})_2/\text{L1}$ ] the reaction proceeded in excellent yields in 10–25 minutes (entries 1 and 2, **Table 1**).

As known, the base shows an important role in this reaction, so various bases were investigated (entries 2, 4–6, **Table 1**). Among the bases employed,  $\text{K}_3\text{PO}_4$  and  $\text{K}_2\text{CO}_3$  were found to be the best in the present protocol (entries 2 and 4, **Table 1**). However, with  $\text{K}_3\text{PO}_4$  the coupling reaction proceeded in a reduced time in comparison with  $\text{K}_2\text{CO}_3$ .

Keeping the catalyst, base, and ligand **L1** constant and using different solvents such as  $\text{MeOH}/\text{H}_2\text{O}$ ,  $\text{MeOH}$ ,  $\text{EtOH}$ , and  $\text{EtOH}/\text{H}_2\text{O}$ , the desired product was obtained in 70–99% yields (entries 7–10, **Table 1**). As was evidenced in **Table 1** entry 8, the reaction afforded biphenyl in an excellent yield after 5 minutes in water, proving to be the best medium for this catalyst system. We then evaluated the reaction in the absence of TBAB (entry 11, **Table 1**), and we observed excellent yields in 10 minutes.

We have also studied the influence of ligands **L2** and **L3** on catalytic activity and tested the ligand **L2** and **L3** under the same reaction conditions as for **L1**. The results are summarized in **Table 1** (entries 12 and 13). As can be observed, ligands **L1** and **L3** shows similar catalytic activity (entries 11 and 13, **Table 1**), but the reaction time is shorter using **L1**.

Once the best ligand (**L1**) and appropriate solvent and base were identified, different palladium sources such as  $\text{Pd}(\text{CNPh})_2\text{Cl}_2$  and  $\text{Pd}(\text{PPh}_3)_2\text{Cl}_2$  (entries 14 and 15, **Table 1**) were tested and **4a** was obtained in good yields; however, these yields did not exceed the efficiency of  $\text{Pd}(\text{OAc})_2$  (entry 11, **Table 1**).

Finally, in order to use even less catalyst, we carried out the reaction using 0.25 mol% and 0.1 mol% of the catalytic system [ $\text{Pd}(\text{OAc})_2/\text{L1}$ ] (entries 16 and 17, **Table 1**) and the best yield was obtained when 0.25 mol% was used. Thus, optimized conditions for this cross-coupling reaction involves the use of 0.25 mol% of the catalyst  $\text{H}_2\text{O}$  as solvent,  $\text{K}_3\text{PO}_4$  as base, in the absence of TBAB under IR irradiation.

Furthermore, when the reaction is carried out under reflux conditions using conventional heating (entry 18, **Table 1**), we obtained an excellent yield of the coupling product **4a** in a longer time. The same reaction was performed at room temperature and achieved **4a** in 76% yield, after 12 h (entry 19, **Table 1**). In absence of ligand, we obtained a 20% yield (entry 20, **Table 1**) which indicated the essential role of the hydrazone ligand.

In an effort to understand the role of the molecular structure in the complex between the hydrazone **L1** and  $\text{Pd}(\text{OAc})_2$ , we attempted to isolate the complex under different reaction conditions. In all cases we observed complete consumption of the ligand;

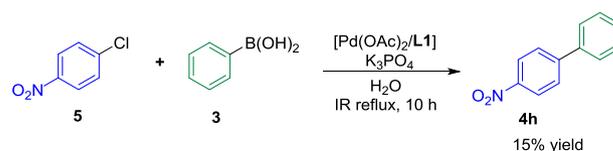

however, we were not successful in isolating the complex in any case. Based on our experience, we believe that the hydrazone behaves as an [N,N] ligand, as in other structurally similar hydrazone ligands we have detected [34].

Additionally, we tried to preformed the complex between hydrazone **L1** and  $\text{Pd}(\text{OAc})_2$  (entry 21, **Table 1**) before adding the substrates and base; then, the reaction mixture was refluxed under IR irradiation and the Suzuki-Miyaura product was obtained in 95% yield. A similar yield resulted when the reaction was performed in one pot (entry 16, **Table 1**).

With a reliable set of conditions in hand (entry 16, **Table 1**), the scope and generality of the developed protocol with respect to various aryl bromides and phenylboronic acids were investigated using our catalytic system [ $\text{Pd}(\text{OAc})_2/\text{L1}$ ]. When phenylboronic acid was coupled with several aryl bromides containing both electron-donating and electron-withdrawing groups, the corresponding products were obtained in excellent yields (entries 1–8, **Table 2**). Due to the steric hindrance of 4-bromotoluene, 2-bromotoluene and 2-bromo-1,3-dimethylbenzene, the desired products were obtained in good yields (entries 3–5, **Table 2**). Similarly, when bromobenzene was coupled with several phenylboronic acids containing both electron-donating and electron-withdrawing groups, the reaction proceeded in excellent yields and similar reaction times (entries 9–11, **Table 2**) in comparison with other aryl bromides.

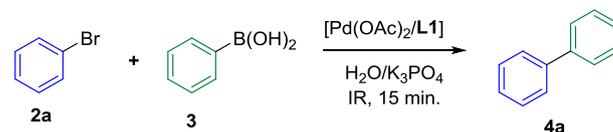

We also investigated the reaction of heteroaryl bromides and aryl chlorides. The Suzuki-Miyaura cross-coupling reaction of heteroaryl halides such as 2-bromopyridine, 3-bromopyridine, 2-bromothiophene and 3-bromothiophene with phenylboronic acid gave the corresponding coupled products in a good yields (entries 12–15, **Table 2**), but we observed that the coupling reaction required extended reaction times.

In attempt to extend this methodology to aryl chlorides, we also conducted the coupling of 4-nitrochlorobenzene with phenylboronic acid in the optimized conditions for aryl bromides, but

**Scheme 2.** Suzuki-Miyaura reaction using 4-nitrochlorobenzene.

**Table 3**  
Recycling of the catalyst.

Cycle	Yields (%) <sup>a</sup>	TON <sup>b</sup>	TOF (h <sup>-1</sup> ) <sup>c</sup>
1	95	380	1520

4	60	240	960
5	45	180	720
6	15	68	240

Reaction condition: Aryl halide **2** (0.5 mmol), phenylboronic acid (**3**) (0.6 mmol),  $\text{H}_2\text{O}$  (3 mL),  $\text{K}_3\text{PO}_4$  (1 mmol), [ $\text{Pd}(\text{OAc})_2/\text{L1}$ ] = 0.25% mol,  $T = 96^\circ\text{C}$ ,  $t = 15$  min.

<sup>a</sup> Isolated yields.

<sup>b</sup> TON = ratio of moles of product formed to moles of catalyst used.

<sup>c</sup> TOF = TON/ $t$  (h).

**Table 4**  
Catalytic performance of different catalysts in the Suzuki-Miyaura cross-coupling reaction.

Entry	Catalyst (% mol)	Conditions	Time	Yield	Ref
1	$\beta$ -cyclodextrin-Pd(II) complex (3)	K <sub>2</sub> CO <sub>3</sub> , H <sub>2</sub> O, rt	50 min	75	[24b]
2	[NHC-Pd(II) complex] (0.2)	K <sub>3</sub> PO <sub>4</sub> ·3H <sub>2</sub> O, H <sub>2</sub> O, TBAB, 40 °C	6 h	90	[25e]
3	ligand free-Pd(OAc) <sub>2</sub> (5)	Stilbazo (5 mol%), K <sub>2</sub> CO <sub>3</sub> , H <sub>2</sub> O, rt	4 h	92	[25d]
4	ligand free-PdCl <sub>2</sub> (2)	Na <sub>2</sub> SO <sub>4</sub> (8 mol%), K <sub>2</sub> CO <sub>3</sub> , <i>i</i> -PrOH or H <sub>2</sub> O, rt	7h	98	[28]
5	N-heterocyclic carbene-Pd (II) (0.1)	CS <sub>2</sub> CO <sub>3</sub> , H <sub>2</sub> O, 80 °C.	24 h	99	[29b]
6	L-arginine/PdCl <sub>2</sub> (0.01)	H <sub>2</sub> O/EtOH, rt	1 h	96	[30a]
7	[imidazole-hydrazone/Pd(OAc) <sub>2</sub> ] (0.25)	H <sub>2</sub> O, K <sub>3</sub> PO <sub>4</sub> , 96 °C	15 min	99	this work

unfortunately, the corresponding coupling product was not detected, even when we raised the Pd loading up to 0.1 mol % and a reaction time to 10 h (Scheme 2), only 15% yield was achieved.

In order to observe the recycling capacity of the catalytic system [Pd(OAc)<sub>2</sub>/L1], we conducted the coupling between bromobenzene and phenylboronic acid under the optimal reaction conditions (Table 3). A flask was charged with bromobenzene, phenylboronic acid, the catalytic system [Pd(OAc)<sub>2</sub>/L1], K<sub>3</sub>PO<sub>4</sub>, and water. The mixture in open air was irradiated under IR irradiation for 15 minutes. After the mixture was cooled, the aqueous layer was extracted with *n*-hexane (3 × 5 mL) and the flask was charged again with bromobenzene, phenylboronic acid, and K<sub>3</sub>PO<sub>4</sub>. Each time after cooling and extraction with *n*-hexane, the reagents and base were added, and the reaction was repeated. The recovered catalyst was successfully reused in the subsequent three cycles, and the coupled product was obtained in good yields (entries 1–3, Table 3). Nevertheless, the yield of coupled product dropped significantly in the fourth and fifth cycles (entries 4 and 5). Lastly, a drastic decrease was observed in the six run (entry 6, Table 3) probably due to decomposition of the catalyst system [Pd(OAc)<sub>2</sub>/L1].

Finally, we made a comparison of the activity of various Pd catalysts in water [Pd(OAc)<sub>2</sub>/L1] catalytic system in the Suzuki-Miyaura coupling reaction and found that this catalyst system is advantageous in terms of lower reaction times (entries 1–6, Table 4), low catalyst loading (entries 1, 3, 4 and 6, Table 4) and the absence of additives (entries 2–4, Table 4).

#### 4. Conclusions

In conclusion, we have developed a series of ligands, imidazole-hydrazone L1–L3, which were easy to prepare from inexpensive and commercially available starting materials. The catalyst system derived from these ligands and Pd(OAc)<sub>2</sub> efficiently promotes Suzuki-Miyaura cross coupling reactions, under mild conditions using aryl and heteroaryl halides. A wide range of substrates could be coupled with phenylboronic acid to afford the desired products in good to excellent yields at low catalyst loadings and short reaction times. Overall, the present protocol offers a mild, efficient and attractive alternative to the existing methods because of its broad substrate scope and use of water as solvent.
