

Introduction

I hope you enjoyed last quarter's issue and we have piqued your interest and challenged you as you consider the optimal management for patients with complex anterior instability. We have set the stage in the last issue and now will present the many options available for patients who have anterior instability with significant bone loss.

The Latarjet has emerged as the go-to option; however, there are many other procedures that may be better suited for some cases. We will present the Latarjet both open and arthroscopically and then also offer many other options with both allograft and autograft that can address the bone loss specifically yet preserve the coracoid and the conjoint tendon.

There are many different surgical options available. I believe that many have been well described here and I hope after studying the manuscripts, you have a greater understanding of the indications and techniques.

It has been our goal with these 2 issues to provide you with a comprehensive periodical that will serve as a resource for many years to come.
