## Abstract

This work is concerned with the search for new luminescent materials emitting in the orange-red color. We have synthesized  $\text{YPO}_4$  doped with  $\text{Gd}^{3+}0.25\%$  and/or  $\text{Eu}^{3+}0.50\%$  by hydrothermal method and  $\text{YP}_3\text{O}_9$  doped with  $\text{Sm}^{3+}0.25\%$  and/or  $\text{Eu}^{3+}0.50\%$  by ultraphosphate decomposition reaction. Phase purity was checked by FTIR and XRD. Excitation and emission spectra and fluorescence decay measurements were recorded at room temperature (RT). Emission spectra allow to determine the site symmetry of rare earth ( $\text{RE}^{3+}$ ) in the crystallographic structure of matrices. Weak  $\text{Eu}^{3+}$  emission is detected from  $\text{YPO}_4:\text{Gd}^{3+}$ ,  $\text{Eu}^{3+}$  under excitation at 273 nm.  $\text{Sm}^{3+}$  levels were detected in excitation spectrum of  $\text{YP}_3\text{O}_9:\text{Sm}^{3+}$ ,  $\text{Eu}^{3+}$  monitoring  $\text{Eu}^{3+}$  principal emission at 618 nm. Excited states lifetimes of  $\text{Gd}^{3+}$  and  $\text{Sm}^{3+}$  sensitizers (S) decrease from mono-doped to co-doped matrices indicating an Energy transfers (ET) from S to  $\text{Eu}^{3+}$  with a rate higher than 19%.

**Keywords** Phosphate · Hydrothermal · Flux · Luminescence · Energy transfer ·  $\text{Eu}^{3+}$

## Introduction

In the framework of research of new orange-red phosphors with quantum efficiency (QE) higher than 1 for Hg-free fluorescent lamps and plasma display panels (PDP), ET from  $\text{Gd}^{3+}$  to  $\text{Eu}^{3+}$  in  $\text{YPO}_4$  and from  $\text{Sm}^{3+}$  to  $\text{Eu}^{3+}$  in  $\text{YP}_3\text{O}_9$  are studied. Quantum Cutting (QC) which is a process of ET and cross relaxation (CR) between ions, leads to QE higher than 1 because of the emission of two photons against the absorption of one photon [1]. QC based on ( $\text{Gd}^{3+}$ ,  $\text{Eu}^{3+}$ ) couple of ions where  $\text{Eu}^{3+}$  is the activator (A), was first successfully studied in  $\text{LiGdF}_4$  by Wegh [2]. Then, it was widely studied in fluorides and other materials [3, 4]. In this process, we report  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$  ET which consists of  $^8\text{S}_{7/2} \rightarrow ^6\text{I}_J$   $\text{Gd}^{3+}$  excitation, then  $^6\text{P}_J$  ( $\text{Gd}^{3+}$ )  $\rightarrow ^5\text{H}_J$  ( $\text{Eu}^{3+}$ ) ET. Finally,  $^6\text{P}_J \rightarrow ^8\text{S}_{7/2}$  and  $^5\text{D}_0 \rightarrow ^7\text{F}_J$  transitions respectively of UV and red emissions. The choose of  $\text{YPO}_4$  is due to its physico-chemical

properties. It is a stoichiometric matrix characterized by large band gap equal to 8.6 eV [5] and high thermal stability (up to 1450 °C [6]). The crystal structure is chains constituted alternatively of  $\text{YO}_8$  dodecahedra and  $\text{PO}_4$  tetrahedra. Rare earth ( $\text{RE}^{3+}$ ) ions occupy one type of site and the minimal distance between them is equal to 0.3755 nm [7].  $\text{YPO}_4$  co-doped with  $\text{Tb}^{3+}\text{-Yb}^{3+}$  or  $\text{Tm}^{3+}\text{-Yb}^{3+}$  is near-infrared QC (NIR-QC) phosphor with  $\text{QE} > 172\%$  [4]. Moreover, luminescent nanomaterials using  $\text{YPO}_4$  as host have been widely used in displays, cathode ray tube, and high-pressure mercury lamp, etc. [8]. To our knowledge, QC based on ( $\text{Sm}^{3+}$ ,  $\text{Eu}^{3+}$ ) couple of ions where  $\text{Sm}^{3+}$  and  $\text{Eu}^{3+}$  are respectively S and A, was only studied in  $\text{YPO}_4$ ,  $\text{LaP}_5\text{O}_{14}$  and  $\text{LaP}_3\text{O}_9$  in previous work [7].  $\text{Sm}^{3+} \rightarrow \text{Eu}^{3+}$  ET is part of this process and it consists of  $^6\text{H}_{5/2} \rightarrow ^4\text{I}_{9/2}$  excitation. Then  $^4\text{G}_{5/2}$  ( $\text{Sm}^{3+}$ )  $\rightarrow ^5\text{D}_0$  ( $\text{Eu}^{3+}$ ) ET. Finally,  $^4\text{G}_{5/2} \rightarrow ^6\text{H}_J$  and  $^5\text{D}_0 \rightarrow ^7\text{F}_J$  emissions of orange-red photons. The selection of  $\text{YP}_3\text{O}_9$  is based on the calculation of  $\text{Sm}^{3+}$  5d band position which must be above Q level situated at  $53000 \text{ cm}^{-1}$  [7].  $\text{YP}_3\text{O}_9$  is a stoichiometric matrix characterized by a vacuum ultraviolet (VUV) absorption at 145 and 156 nm of  $(\text{PO}_3)_3^{3-}$  group [9],  $\text{RE}^{3+}$  ions occupy four types of site and  $\text{YO}_6$  octahedra are isolated from each other which leads to high concentration quenching [10]. Moreover, this matrix has a high thermal stability (up to 900 °C) [6, 11]. According to QC conditions [7], A ion concentration must be higher than that of S. Therefore, the double concentration

is considered for both matrices. Additionally, The maximal energy of the phonons ( $E_{\max}$ ) must be low in order to reduce the non-radiative transition probabilities. Although it is not the case in our samples ( $E_{\max} \sim 1060 \text{ cm}^{-1}$  for  $\text{YPO}_4$  [12] and  $\sim 1100 \text{ cm}^{-1}$  for  $\text{YP}_3\text{O}_9$  [4]), the phosphates matrices doped  $\text{RE}^{3+}$  have been widely investigated for intended applications [3, 4, 7].

In the field of fluorescent lamps, it is necessary to replace mercury (harmful to the environment) used as a source of UV photons with another rare gas such as Xenon, source of VUV photons. This last gas employed also in PDP, has a low efficiency regarding that of Hg. So, looking for a new VUV-Vis conversion phosphors with QE higher than one, will perform better. As stated earlier, QC process allows to have these efficiencies. In this paper, the aim of constructing such materials which fulfill QC conditions is to study luminescence and ET.

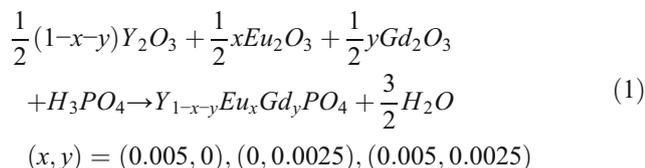

## Experimental

### Rare Earth Phosphates Synthesis

The basic products used for the preparation of samples are the following:  $\text{Y}_2\text{O}_3$  (Rhone-Poulenc, 99.99%),  $\text{Sm}_2\text{O}_3$  (Rhone-Poulenc, 99.99%),  $\text{Eu}_2\text{O}_3$  (Alfa Aesar, 99.99%),  $\text{Gd}_2\text{O}_3$  (Péchiney Saint-Gobain, 99.9%),  $\text{H}_3\text{PO}_4$  (Panreac, 50–51%) and KBr (Shimadzu Corporation). Samples of  $\text{Gd}^{3+}$  and/or  $\text{Eu}^{3+}$  doped  $\text{YPO}_4$  and  $\text{Sm}^{3+}$  and/or  $\text{Eu}^{3+}$  doped  $\text{YP}_3\text{O}_9$  were prepared by using respectively hydrothermal method and ultraphosphate decomposition reaction.

### Hydrothermal Method

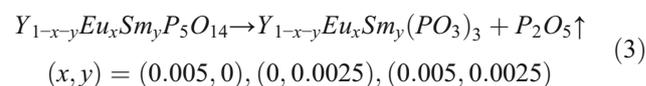

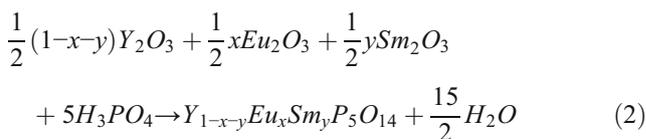

Hydrothermal method is based on reaction between RE oxides (stoichiometric ratios), an excess of orthophosphoric acid and a given amount of water at  $200 \text{ }^\circ\text{C}$  during 4 h within a stainless steel autoclave with a 23 ml Teflon chamber. After the reaction was complete, the autoclave was naturally cooled to RT. Finally, the obtained powder was consecutively washed with hot distilled water, dried at  $100 \text{ }^\circ\text{C}$  in the air and finely grounded [3]. The reaction is expressed in the following equation (Eq. 1):

Obtained powders underwent calcinations at  $850 \text{ }^\circ\text{C}$  and  $1000 \text{ }^\circ\text{C}$  during 2 h (the monophosphates are stable until  $1450 \text{ }^\circ\text{C}$ ).

### Ultraphosphate Decomposition Reaction

$\text{LnP}_5\text{O}_{14}$  ultraphosphates transform to  $\text{Ln}(\text{PO}_3)_3$  polyphosphates when they are calcined at temperatures ranging between  $800$  and  $900 \text{ }^\circ\text{C}$ . First,  $\text{YP}_5\text{O}_{14}$  crystals doped with  $\text{Sm}^{3+}$  and/or  $\text{Eu}^{3+}$  were prepared using Flux method [3] with  $450 \text{ }^\circ\text{C}$  for 150 h as conditions. Then, transparent crystals of some millimeters were properly grounded to powder. Finally, the ultraphosphate decomposition reaction [11] was used to develop yttrium polyphosphates at  $870 \text{ }^\circ\text{C}$  for 4 h in air atmosphere (according to Agrawal et al. [6], the decomposition temperature is  $860 \pm 10 \text{ }^\circ\text{C}$ ). The reaction Eq 3. are:

Yttrium polyphosphate powders underwent calcinations at  $900 \text{ }^\circ\text{C}$  for 4 h, then 20 h.

### Instruments and Techniques

All the synthesized samples have been checked by infrared absorption spectroscopy technique (FTIR) between  $4000$  and  $400 \text{ cm}^{-1}$  with a Shimadzu IR-8400S FTIR spectrometer. The purity of compounds was controlled by X-ray diffraction (XRD) using a Bruker D8 Advance spectrometer with  $\text{CuK}\alpha 1$  radiation ( $\lambda = 1.54060 \text{ \AA}$ ). Excitation and emission spectra were recorded using HORIBA Jobin Yvon FluoroMax-4 spectrofluorometer equipped with 150 W ozone-free Xenon arc-lamp. The beam of continuous light ( $200\text{--}950 \text{ nm}$ ) is focused on the entrance slit of the excitation monochromator. Then, it is directed onto a sample, which emits luminescence. The luminescence is directed into a second, emission monochromator, which selects a band of wavelengths, and manages them towards a detector (R928P photomultiplier tube). The signal from the detector which has a response ranges from  $180$  to  $850 \text{ nm}$ , is reported to a system controller and host computer, where the data can be manipulated and presented using FluorEssence software. The spectra were corrected by means of the software. Also, the fluorescence decays were recorded with this spectrofluorometer. All measurements were made at RT, the slits widths were  $0.5/0.5$ ,  $1/1$  and  $5 \text{ mm}/5 \text{ mm}$  and J1939 Cut-On filters were used.

## Results and Discussion

### Structural Characterization

#### Infrared Spectroscopy

In the orthophosphate  $YPO_4$  of zircon structure (xenotime phase),  $PO_4$  tetrahedron is isolated and has two antisymmetric vibration modes active in infrared.  $\nu_3$  mode of P–O stretching appears around  $1080\text{ cm}^{-1}$  and  $\nu_4$  mode of O–P–O deformation appears in the region from  $500$  to  $650\text{ cm}^{-1}$ . Figure 1 shows the FTIR spectra of  $YPO_4$  doped with  $Gd^{3+}$  and/or  $Eu^{3+}$ . The band with three humps at  $1124$ ,  $1070$  and  $1006\text{ cm}^{-1}$  corresponds to  $\nu_3$  mode. The peaks at  $648$  and  $523\text{ cm}^{-1}$  correspond to  $\nu_4$  mode. The band and the peak positions are comparable with reported values [8, 12, 13].

Figure 2 shows FTIR spectra of  $YP_3O_9$  doped with  $Sm^{3+}$  and/or  $Eu^{3+}$ . The absorption bands separated by vertical dashed line and peaked at:  $1259/1234$ ,  $1192/1178/1167/1097$ ,  $1017/945$ ,  $772/747/712/684$  and  $595/540/519/491\text{ cm}^{-1}$  correspond respectively to asymmetric stretching vibrations of OPO (terminal oxygen):  $\nu_{as}(OPO)$ , symmetric stretching vibrations of OPO:  $\nu_s(OPO)$ , asymmetric stretching vibrations of POP (bridging oxygen):  $\nu_{as}(POP)$ , symmetric stretching vibrations of POP:  $\nu_s(POP)$  and deformation vibrations of phosphate and the stretching vibrations of yttrium oxygen bonds:  $\delta(OPO\text{ or }POP)$  &  $\nu(Y-O)$ . These vibrations are assigned to monoclinic polyphosphates with small  $RE^{3+}$  ions ( $Gd-Lu, Y$ ) [14].

#### X-Ray Diffraction Spectroscopy

The XRD patterns of Y-monophosphates are shown in Fig. 3. All the peaks are indexed in the tetragonal zircon-type

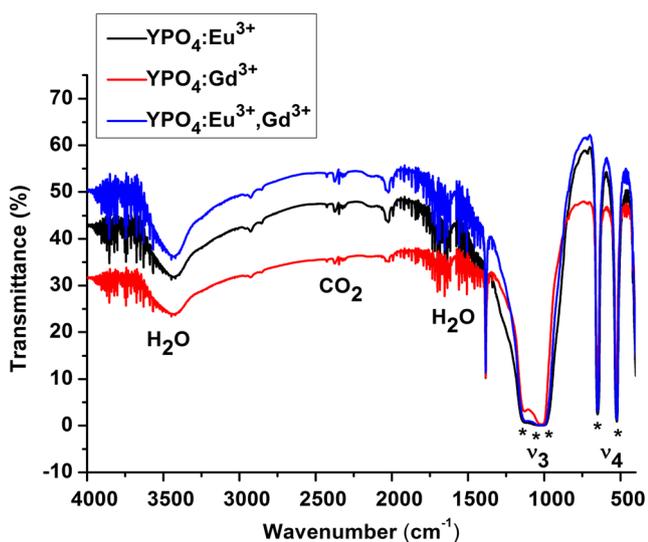

Fig. 1 FTIR spectra of  $YPO_4$  doped with  $Gd^{3+}$  and/or  $Eu^{3+}$ ; (\*) xenotime type. Assignments of vibrational bands are indicated

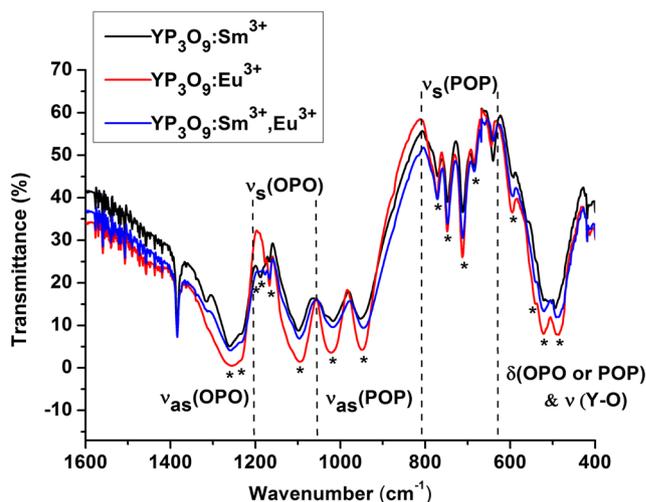

Fig. 2 FTIR spectra of  $YP_3O_9$  doped with  $Sm^{3+}$  and/or  $Eu^{3+}$ ; (\*) polyphosphate type. Assignments of vibrational bands are indicated

structure with space group  $I4_1/amd$  according to the JCPDS 11–0254 file. Concerning Y-polyphosphates purity, all the peaks in Fig. 4 are indexed in the monoclinic system with C space group according to the JCPDS 42–0501 file.

#### UV-Visible Spectroscopy

##### $YPO_4:Gd^{3+}0.25\%, Eu^{3+}0.50\%$

$YPO_4:Eu^{3+}0.50\%$  excitation spectrum monitoring  $^5D_0 \rightarrow ^7F_2$  principal emission at  $618\text{ nm}$ , recorded between  $240$  and  $500\text{ nm}$  using high-pass filter ( $\lambda \geq 500\text{ nm}$ ) is presented by black line in Fig. 5. It consists of a broad band situated below  $250\text{ nm}$  assigned to  $Eu^{3+}$  charge transfer band (CTB) [7] and sharp peaks assigned to  $Eu^{3+}$  intra-4f-transitions:  $^7F_0$  to  $^5I_6$ ,  $^5F_7$ ,  $^5H_7$ ,  $^5D_4$ ,  $^5L_7$ ,  $^5L_6$ ,  $^5D_3$  and  $^5D_2$  [3, 7, 15] situated

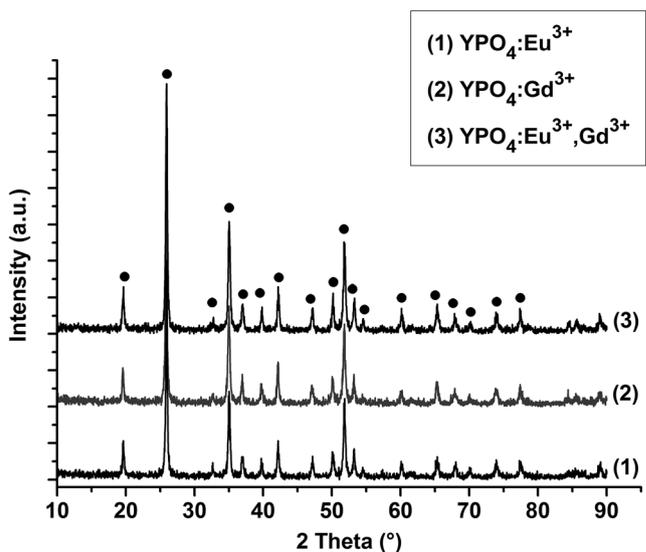

Fig. 3 XRD spectra of  $YPO_4$  doped with  $Gd^{3+}$  and/or  $Eu^{3+}$

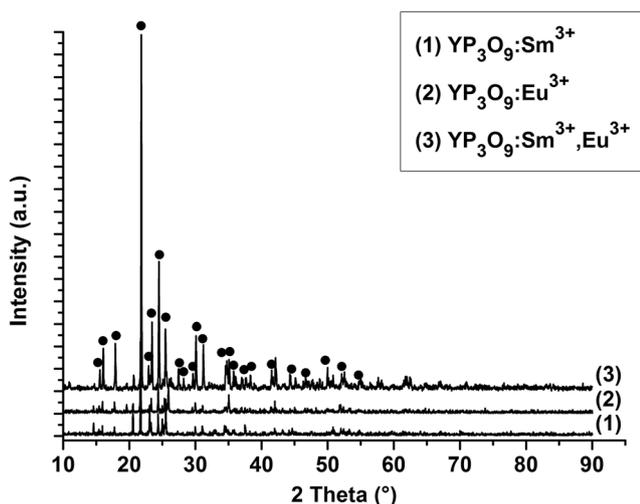

Fig. 4 XRD spectra of  $\text{YP}_3\text{O}_9$  doped with  $\text{Sm}^{3+}$  and/or  $\text{Eu}^{3+}$

respectively at 286, 298, 318, 362, 381, 394, 416 and 465 nm.  $^5\text{L}_6$  level has the highest intensity,  $\text{Eu}^{3+}$  ion can be excited at this level or at CTB.

The emission spectrum under excitation at 394 nm  $^5\text{L}_6$  level shown in Fig. 6, is composed by sharp bands situated in the orange-red region and centered at 591, 618, 649 and 695 nm assigned respectively to  $^5\text{D}_0 \rightarrow ^7\text{F}_1$  Magnetic Dipole Transition (MDT) — its intensity is largely independent of environment,  $^5\text{D}_0 \rightarrow ^7\text{F}_2$  hypersensitive Electric Dipole Transition (EDT) — its intensity is very strongly dependent on environment,  $^5\text{D}_0 \rightarrow ^7\text{F}_3$  Forbidden Transition and  $^5\text{D}_0 \rightarrow ^7\text{F}_4$  EDT — its intensity is dependent on environment, but no hypersensitive.  $^5\text{D}_0 \rightarrow ^7\text{F}_0$  EDT not detected in our spectrum is usually located between 570 and 585 nm and only observed in  $C_n$ ,  $C_{nv}$  and  $C_s$  symmetry [7, 16]. Recalling that the site symmetry in  $\text{YPO}_4$  is  $D_{2d}$  [12].

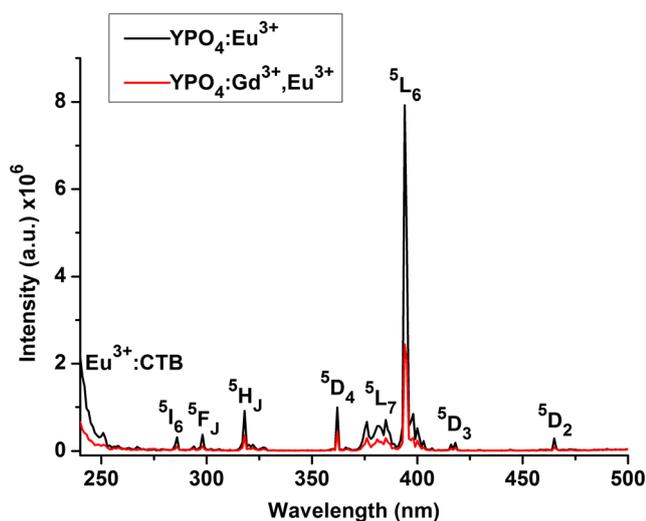

Fig. 5 Excitation spectra of  $\text{YPO}_4:\text{Eu}^{3+}$  and  $\text{YPO}_4:\text{Gd}^{3+},\text{Eu}^{3+}$  monitored at 618 nm

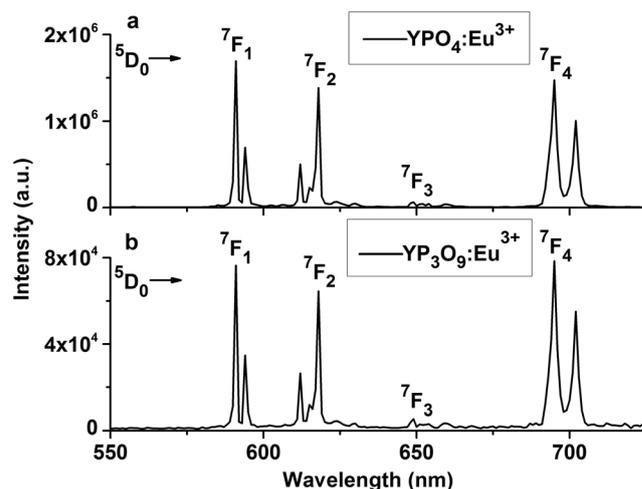

Fig. 6 Emission spectra of (a)  $\text{YPO}_4:\text{Eu}^{3+}$  and (b)  $\text{YP}_3\text{O}_9:\text{Eu}^{3+}$  excited into  $^5\text{L}_6$  level

In a Centro-symmetric site, the main observed transitions are MDT nature, on the contrary, if the site is non Centro-symmetry the EDT are generally more intense [17]. In the Fig. 6,  $^5\text{D}_0 \rightarrow ^7\text{F}_1$  MDT is more intense than  $^5\text{D}_0 \rightarrow ^7\text{F}_{2,4}$  EDT, so  $D_{2d}$  site symmetry of  $\text{Eu}^{3+}$  is Centro-symmetric.

Concerning  $\text{Gd}^{3+}$  mono-doped  $\text{YPO}_4$ , UV emission under excitation into  $^6\text{I}_1$  level at 273 nm is presented by dashed line in Fig. 7 [3, 15].

$\text{YPO}_4:\text{Gd}^{3+}0.25\%$ ,  $\text{Eu}^{3+}0.50\%$  excitation spectrum monitoring  $^5\text{D}_0 \rightarrow ^7\text{F}_2$  transition at 618 nm is presented in Fig. 5 (red line). It consists of only  $\text{Eu}^{3+}$  4f levels and no  $\text{Gd}^{3+}$  levels. The no distinction of  $\text{Gd}^{3+}$  levels is due to its low concentration. In previous work,  $^6\text{I}_1$ ,  $^6\text{P}_1$  and  $^6\text{D}_1$  levels of  $\text{Gd}^{3+}$  were observed in the excitation spectra of  $\text{GdPO}_4:\text{Eu}^{3+x}\%$  ( $x = 1, 7$  and 10) [3]. In the case of  $\text{Gd}^{3+}$ -based phosphate mono-doped with  $\text{Eu}^{3+}$ , the  $\text{Gd}^{3+}$  4f levels appeared in the excitation

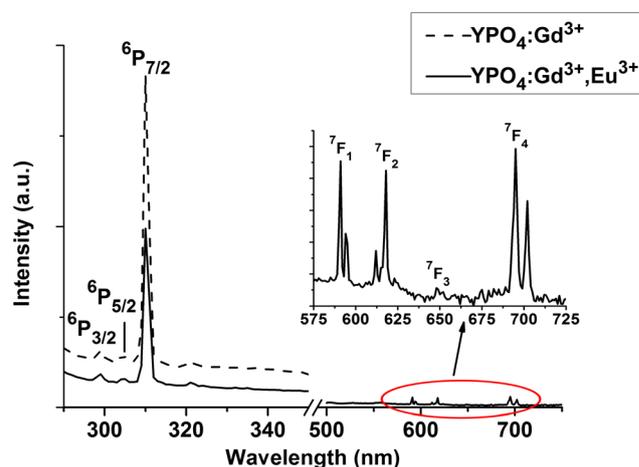

Fig. 7 Emission spectra of  $\text{YPO}_4:\text{Gd}^{3+}$  and  $\text{YPO}_4:\text{Gd}^{3+},\text{Eu}^{3+}$  excited into  $^6\text{I}_1$  at 273 nm. The inset shows an enlargement of the region from 575 to 725 nm

spectrum monitoring  $\text{Eu}^{3+}$  emission. Otherwise, these levels are not distinguished for  $\text{Gd}^{3+}$  low concentration in such phosphates.

To prove  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$  ET, the emission spectrum of  $\text{YPO}_4:\text{Gd}^{3+}0.25\%, \text{Eu}^{3+}0.50\%$  excited into  ${}^6\text{I}_J$  at 273 nm was recorded (solid line, Fig. 7). UV emission is decreased to half compared with  $\text{Gd}^{3+}$  mono-doped matrix. Weak  $\text{Eu}^{3+}$  emission corresponding to  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_J$  is detected, indicating an expected ET occurs. Figure 8 describes the  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$  ET pathway. Noting that no  $\text{Eu}^{3+}$  emission is observed for mono-doped matrix under excitation at 273 nm.

ET is a type of interaction between  $\text{RE}^{3+}$  ions. When concentration increases, the distance between  $\text{RE}^{3+}$  decreases which lead to ET. This later occurs because of S and A 4f energy levels are energetically close to each other.  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$  ET has been pointed out in literature [18]. It was reported that this ET is non-radiative and its rate increases with increasing  $\text{Eu}^{3+}$  concentration for an optimum concentration of  $\text{Gd}^{3+}$ .

In  $\text{YPO}_4$ ,  $\text{Gd}^{3+} {}^6\text{P}_{7/2}$  level situated at  $32258 \text{ cm}^{-1}$  is close to  $\text{Eu}^{3+} {}^5\text{H}_J$  level situated at  $31446 \text{ cm}^{-1}$  (Fig. 8). Precisely, the gap between these two levels (equal to  $812 \text{ cm}^{-1}$ ) is less than  $E_{\text{max}}$  which results in a resonant non-radiative energy transfer (NRET). Afterwards a non-radiative decay of  ${}^5\text{H}_J$  to  ${}^5\text{D}_0$  which emits in turn simultaneously with  $\text{Gd}^{3+}$  emission of  ${}^6\text{P}_J \rightarrow {}^8\text{S}_{7/2}$  transitions.

**$\text{YP}_3\text{O}_9:\text{Sm}^{3+}0.25\%, \text{Eu}^{3+}0.50\%$**

The excitation spectrum of  $\text{Sm}^{3+}$  mono-doped  $\text{YP}_3\text{O}_9$  monitored at 602 nm ( ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_{7/2}$  principal transition) and recorded between 240 nm and 500 nm using high-pass filter ( $\lambda \geq 500 \text{ nm}$ ), is presented in Fig. 9. The spectrum contains sharp peaks situated at 304, 317, 332, 343, 360, 374, 390, 401,

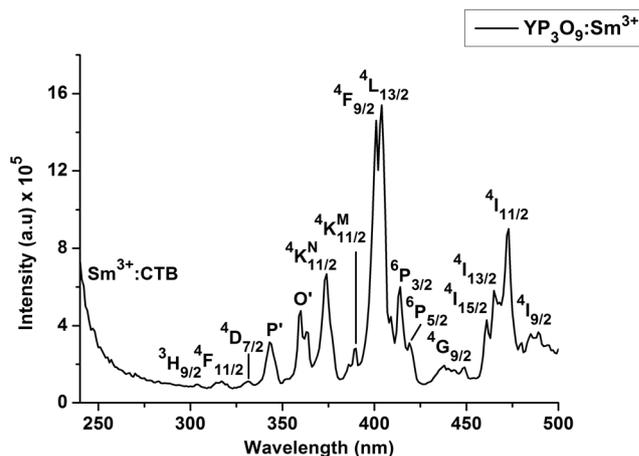

Fig. 9 Excitation spectrum of  $\text{YP}_3\text{O}_9:\text{Sm}^{3+}$  monitored at 602 nm

404, 414, 419, 438, 461, 465, 473 and 480 nm assigned respectively to  ${}^3\text{H}_{9/2}, {}^4\text{F}_{11/2}, {}^4\text{D}_{7/2}, \text{P}', \text{O}', {}^4\text{K}_{11/2}^{\text{N}}, {}^4\text{K}_{11/2}^{\text{M}}, {}^4\text{F}_{9/2}, {}^4\text{L}_{13/2}, {}^6\text{P}_{3/2}, {}^6\text{P}_{5/2}, {}^4\text{G}_{9/2}, {}^4\text{I}_{13/2}, {}^4\text{I}_{15/2}, {}^4\text{I}_{11/2}$  and  ${}^4\text{I}_{9/2}$  4f energy levels [7, 15] and a broad band situated below 260 nm assigned to CTB [19].

Emission spectrum of this sample, under excitation into  ${}^4\text{L}_{13/2}$  level most absorbing (404 nm) presented by black line in Fig. 10, shows four sharp bands centered around 561, 602, 644 and 715 nm corresponding, respectively, to  ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_{5/2}$  MDT,  ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_{7/2}$  partly Magnetic and partly forced Electric Dipole Transition,  ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_{9/2}$  purely EDT sensitive to the crystal field and  ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_{11/2}$  EDT [19]. Generally, the intensity ratio of EDT ( ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_{9/2}$ ) and MDT ( ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_{5/2}$ ) of  $\text{Sm}^{3+}$  ion can be used to understand the symmetry of the local environment of trivalent 4f ions in the host matrix investigated. The asymmetric nature is more prominent when the intensity of the EDT is higher. The ratio value below or above 1.0 indicates the symmetric or

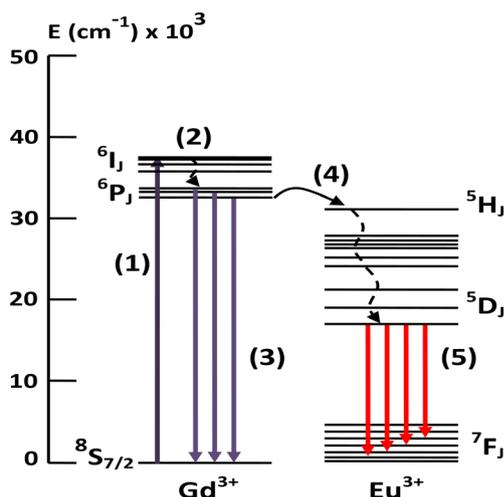

Fig. 8 Energy level diagrams of  $\text{Gd}^{3+}$  and  $\text{Eu}^{3+}$  in  $\text{YPO}_4$ : (1)  $\text{Gd}^{3+}$  Excitation, (2) Non-radiative decay, (3)  $\text{Gd}^{3+}$  emission, (4) NRET followed by non-radiative decay of  ${}^5\text{H}_J$  and (5)  $\text{Eu}^{3+}$  emission.  ${}^5\text{D}_0$  energy position is taken from reference [15]

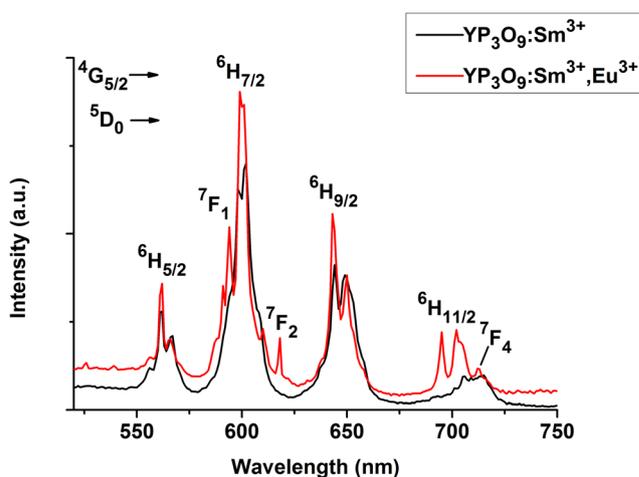

Fig. 10 Emission spectra of  $\text{YP}_3\text{O}_9:\text{Sm}^{3+}$  excited into  ${}^4\text{L}_{13/2}$  level (black line) and  $\text{YP}_3\text{O}_9:\text{Sm}^{3+}, \text{Eu}^{3+}$  excited into  ${}^4\text{I}_{9/2}$  level (red line)

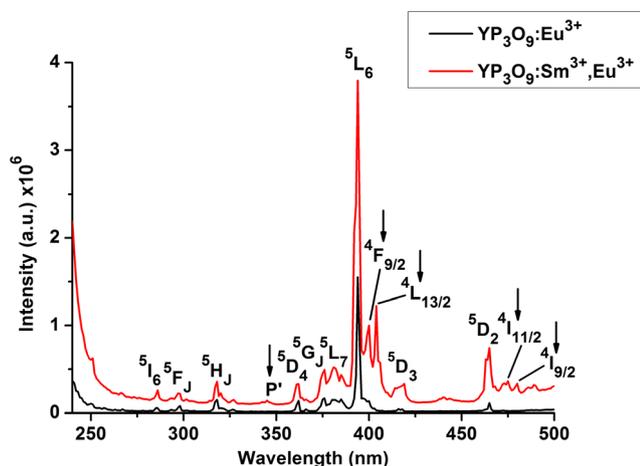

asymmetric nature of host matrix [19]. According to emission spectrum of  $\text{YP}_3\text{O}_9:\text{Sm}^{3+}$ , the ratio of intensity between EDT per MDT is above 1.0 which indicates an asymmetric nature of this matrix. Besides, the existence of four  $\text{RE}^{3+}$  sites in the crystal structure.

Concerning  $\text{YP}_3\text{O}_9:\text{Eu}^{3+}$ , Excitation spectrum monitoring  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_2$  transition at 618 nm shown in Fig. 11 (black line) is divided into two parts. The first part contains a band situated below 260 nm assigned to CTB [9]. In the second part, there are sharp peaks situated at 285, 298, 318, 362, 376, 382, 394, 416 and 465 nm respectively assigned to  ${}^5\text{I}_6$ ,  ${}^5\text{F}_7$ ,  ${}^5\text{H}_7$ ,  ${}^5\text{D}_4$ ,  ${}^5\text{G}_7$ ,  ${}^5\text{L}_7$ ,  ${}^5\text{L}_6$ ,  ${}^5\text{D}_3$  and  ${}^5\text{D}_2$  4f energy levels [7, 15].

$\text{YP}_3\text{O}_9:\text{Eu}^{3+}$  emission spectrum under excitation into  ${}^5\text{L}_6$  level presented in the above Fig. 6, is composed by sharp bands centered around 591, 618, 648, 695 nm assigned respectively to  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_1$  MDT,  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_2$  EDT,  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_3$  Forbidden Transition and  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_4$  EDT [10, 16]. Emission of  $\text{Eu}^{3+}$  is more intense than that of  $\text{Sm}^{3+}$  and both are situated in the orange-red region. Also by comparing the spectra of Fig. 6,  $\text{Eu}^{3+}$  fluorescence in Y-monophosphate is more intense than in Y-polyphosphate.

There are four non-equivalent  $\text{Eu}^{3+}$  sites in monoclinic  $\text{YP}_3\text{O}_9$ . Two types of sites without inversion symmetry (low symmetry) and two sites with inversion symmetry (high symmetry) [9, 10]. It is known that  $\text{Eu}^{3+}$  is sensitive to the crystal field environment. When  $\text{Eu}^{3+}$  occupies the low symmetry sites, its  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_2$  EDT would be lifted and has the high emissive intensity. Otherwise, if  $\text{Eu}^{3+}$  occupies the high symmetry sites, the strongest emissive peak of  $\text{Eu}^{3+}$  is the  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_1$  allowed transition [9]. The analysis of the spectrum shows that  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_1$  is the most intense indicating that  $\text{Eu}^{3+}$  occupies two high symmetric sites.

Excitation spectrum of  $\text{YP}_3\text{O}_9:\text{Sm}^{3+}0.25\%$ ,  $\text{Eu}^{3+}0.50\%$ , monitoring  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_2$ :  $\text{Eu}^{3+}$  emission at 618 nm shown in Fig. 11 (red line), consists of  $\text{Sm}^{3+}$  and  $\text{Eu}^{3+}$  4f energy levels.

**Fig. 11** Excitation spectra of  $\text{YP}_3\text{O}_9:\text{Eu}^{3+}$  and  $\text{YP}_3\text{O}_9:\text{Sm}^{3+}$ ,  $\text{Eu}^{3+}$  monitored at 618 nm

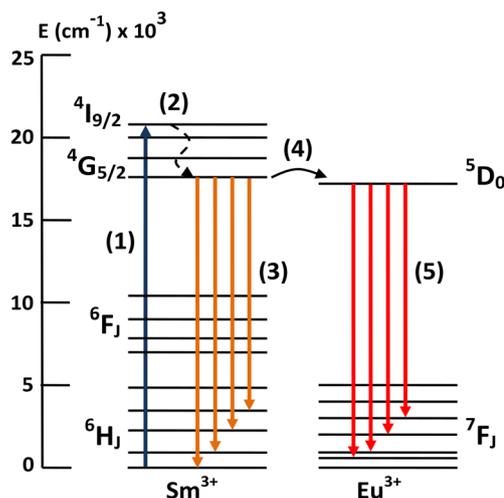

The observation of  $\text{Sm}^{3+}$  level ( $\text{P}'$ : 345,  ${}^4\text{F}_{9/2}$ : 400,  ${}^4\text{L}_{13/2}$ : 404,  ${}^4\text{I}_{11/2}$ : 475 and  ${}^4\text{I}_{9/2}$ : 480 nm) indicates that  $\text{Sm}^{3+} \rightarrow \text{Eu}^{3+}$  ET occurs [7]. The observed peak intensities are weak due to low doping concentrations which leads to low ET. The emission spectrum of co-doped matrix under excitation into  ${}^4\text{I}_{9/2}$   $\text{Sm}^{3+}$  level at 480 nm shown in Fig. 10, is composed by the emissions of both types of ions (it seems that  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_3$  transition is hidden by  $\text{Sm}^{3+}$  emission). The observation of  $\text{Eu}^{3+}$  emission bands situated at 594 ( ${}^5\text{D}_0 \rightarrow {}^7\text{F}_1$ ), 617 ( ${}^5\text{D}_0 \rightarrow {}^7\text{F}_2$ ) and 702 nm ( ${}^5\text{D}_0 \rightarrow {}^7\text{F}_4$ ) indicates that an expected ET from  $\text{Sm}^{3+}$  to  $\text{Eu}^{3+}$  occurs and the pathway is described in Fig. 12. It is noted that no emission was detected in  $\text{YP}_3\text{O}_9:\text{Eu}^{3+}$  under excitation at 480 nm.  ${}^4\text{G}_{5/2}$  energy position is equal to  $17825 \text{ cm}^{-1}$  and  ${}^5\text{D}_0$  energy position range is  $17094\text{--}17544 \text{ cm}^{-1}$ . It is clear that the gap between these levels is less than  $E_{\text{max}}$ , so the observed ET is phonon assisted [7].

### Fluorescence Decay

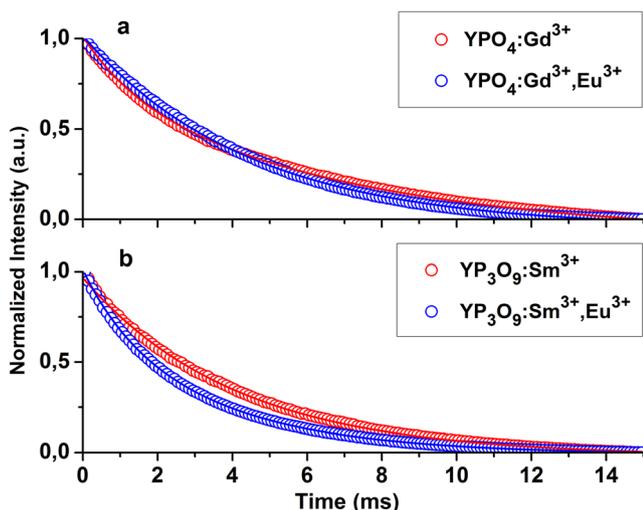

The curves in Fig. 13 present the fluorescence decays of  $\text{YPO}_4:\text{Gd}^{3+}0.25\%$  and  $\text{YPO}_4:\text{Gd}^{3+}0.25\%$ ,  $\text{Eu}^{3+}0.50\%$  of  ${}^6\text{P}_{7/2} \rightarrow {}^8\text{S}_{7/2}$  emission at 310 nm under excitation into  ${}^6\text{I}_J$  level at 273 nm.  $\text{YPO}_4:\text{Gd}^{3+}0.25\%$  decay follows a bi-exponential function represented by:

$$I(t) = I_1 e^{-t/\tau_1} + I_2 e^{-t/\tau_2} + C \quad (4)$$

where  $I$  is phosphorescence intensity,  $I_1$  and  $I_2$  are the intensities at two different interval times and the corresponding decay times are  $\tau_1$  and  $\tau_2$ ,  $t$  is time and  $C$  is constant. The

**Fig. 12** Energy level diagrams of  $\text{Sm}^{3+}$  and  $\text{Eu}^{3+}$ . (1) Excitation into  ${}^4\text{I}_{9/2}$  of  $\text{Sm}^{3+}$  ion, (2) Non-radiative decay of  ${}^4\text{I}_{9/2}$  to  ${}^4\text{G}_{5/2}$ , (3)  $\text{Sm}^{3+}$  emission of  ${}^4\text{G}_{5/2} \rightarrow {}^6\text{H}_J$  transitions, (4) NRET —  ${}^4\text{G}_{5/2}$  and  ${}^5\text{D}_0$  levels are energetically close to each other which results in a resonant non-radiative transfer of excitation energy, (5)  $\text{Eu}^{3+}$  emission of  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_J$  transitions.  ${}^5\text{D}_0$  energy position is taken from reference [15]

**Fig. 13** Fluorescence decays of (a) YPO<sub>4</sub>:Gd<sup>3+</sup> and YPO<sub>4</sub>:Gd<sup>3+</sup>, Eu<sup>3+</sup> at 310 nm emission of Gd<sup>3+</sup> under excitation into <sup>6</sup>I<sub>1</sub> level at 273 nm and (b) YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup> and YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup>, Eu<sup>3+</sup> at 602 nm emission of Sm<sup>3+</sup> under excitation into <sup>4</sup>I<sub>9/2</sub> level at 480 nm. The circles indicate the experimental data, and the solid lines are fitting curves

average decay time  $\tau_{Gd}$  is calculated using the Eq. (5) [20]. Table 1 lists the values of S decay times and ET rates in samples,  $\tau_{Gd}$  is long.

$$\tau_{moy} = \frac{I_1\tau_1 + I_2\tau_2}{I_1 + I_2} \tag{5}$$

Concerning co-doped matrix decay, it follows a mono-exponential function represented by:

$$I(t) = I_0 e^{-\frac{t}{\tau}} + C_0 \tag{6}$$

where  $I_0$  and  $C_0$  are constants and  $\tau$  is lifetime of excited level.  $\tau_{Gd,Eu} < \tau_{Gd}$  which indicates a Gd<sup>3+</sup> → Eu<sup>3+</sup> ET with an ET rate  $\eta_T$  equal to 19% calculated by using the following formula [7]:

$$\eta_T = 1 - \frac{\tau_{S,A}}{\tau_S} \tag{7}$$

Where  $\tau_{S,A}$  and  $\tau_S$  are S lifetimes respectively in co-doped and mono-doped matrices.

**Table 1** S decay times and ET rates in samples

Sample	Decay time (ms)	$\eta_T$
YPO <sub>4</sub> :Gd <sup>3+</sup>	$\tau_{Gd} = 5.51$	19%
YPO <sub>4</sub> :Gd <sup>3+</sup> ,Eu <sup>3+</sup>	$\tau_{Gd,Eu} = 4.45$	
YP <sub>3</sub> O <sub>9</sub> :Sm <sup>3+</sup>	$\tau_{Sm} = 4.07$	28%
YP <sub>3</sub> O <sub>9</sub> :Sm <sup>3+</sup> ,Eu <sup>3+</sup>	$\tau_{Sm,Eu} = 2.95$	

Figure 13 (b) shows fluorescence decay curves of YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup>0.25% and YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup>0.25%, Eu<sup>3+</sup>0.50% of <sup>4</sup>G<sub>5/2</sub> → <sup>6</sup>H<sub>7/2</sub> emission at 602 nm under excitation into <sup>4</sup>I<sub>9/2</sub> level at 480 nm. YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup>0.25% decay follows a mono-exponential function with a decay time equal to 4.07 ms (Table 1). Generally, phosphors activated by Sm<sup>3+</sup> ion have a long lifetime for low concentration [19]. YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup>0.25%, Eu<sup>3+</sup>0.50% decay follows a bi-exponential function. The change of donor fluorescence decay profile is related to ET. The average decay time  $\tau_{Sm,Eu}$  is smaller than  $\tau_{Sm}$ , indicating the occur of Sm<sup>3+</sup> → Eu<sup>3+</sup> efficient ET with  $\eta_T$  equal to 28%.

It is known from the classical Foster–Dexter theory of ET between two electrostatically interacting entities, that the efficiency of ET depends critically on the distance between S and A ions and on the overlap factor [7, 21, 22]. Taking into account the fact that the transfer probability, in the case of dipole–dipole interaction, is proportional to  $D^{-6}$  (D being the S-A distance). In YPO<sub>4</sub>, the ET rate is lower than that of YP<sub>3</sub>O<sub>9</sub> although the minimal distance between RE<sup>3+</sup> ions is equal to 0.3755 nm in YPO<sub>4</sub> [7] and it is in the order of 0.561 nm in YP<sub>3</sub>O<sub>9</sub> [23].

### Conclusion

This work is part of research of new visible QC phosphors. We have synthesized YPO<sub>4</sub> doped with Gd<sup>3+</sup> and/or Eu<sup>3+</sup> by hydrothermal method at low temperature and YP<sub>3</sub>O<sub>9</sub> doped with Sm<sup>3+</sup> and/or Eu<sup>3+</sup> by ultraphosphate decomposition reaction at high temperature. The characterization by FTIR and XRD confirm the phase purity of powders. Under excitation at 394 nm using Xenon lamp, YPO<sub>4</sub>:Eu<sup>3+</sup>0.50% and YP<sub>3</sub>O<sub>9</sub>:Eu<sup>3+</sup>0.50% showed an orange-red emission originating from <sup>5</sup>D<sub>0</sub> to <sup>7</sup>F<sub>J</sub> (J=1–4) levels, and that of Y-monophosphate is the strongest. Also, under excitation at 404 nm, YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup>0.25% emits orange-red light corresponding to <sup>4</sup>G<sub>5/2</sub> → <sup>6</sup>H<sub>J</sub> (J=5/2–11/2) transitions. Based on emission spectra, The only crystallographic site in YPO<sub>4</sub> is Centro-symmetric, whereas YP<sub>3</sub>O<sub>9</sub> of four RE<sup>3+</sup> sites is described to have an asymmetric nature. NRET from Gd<sup>3+</sup> to Eu<sup>3+</sup> and from Sm<sup>3+</sup> to Eu<sup>3+</sup> has been demonstrated in these matrices. The rates of Gd<sup>3+</sup> → Eu<sup>3+</sup> and Sm<sup>3+</sup> → Eu<sup>3+</sup> ET are respectively equal to 19% and 28%, despite the low concentrations. In addition, S lifetimes in YPO<sub>4</sub> is long. Thus, YPO<sub>4</sub>:Gd<sup>3+</sup>0.25%, Eu<sup>3+</sup>0.50% is a luminescent material for UV excitation and YP<sub>3</sub>O<sub>9</sub>:Sm<sup>3+</sup>0.25%, Eu<sup>3+</sup>0.50% is a potential orange-red emitting phosphor for Hg-free fluorescent lamps and PDP. Further VUV measurements will be done on this polyphosphate in a near future research.
