We read the statistical interpretation with interest. In the research in which we evaluate the effects of applying acupressure on the pericardium 6 point with a wristband on the level of nausea-vomiting and comfort after an operation, the experiment and control groups have similar characteristics to each other. Groups were evaluated at 0-2, 2-6, 6-12, 12-24, and 24-48 hours after the operation. After statistical analysis, there was a significant difference between the groups in favor of the experimental group. To reinforce the scales, the comfort levels of the groups were also measured, and the comfort level of the experimental group was

higher than that of the control group after the analysis.
