

Scedosporium apiospermum

Jean-Philippe Bouchara^{1,*} and Nicolas Papon¹

¹Groupe d'Etude des Interactions Hôte-Pathogène (GEIH, EA 3142), SFR ICAT 4208, UNIV Angers, UNIV Brest, Angers, France

KEY FACTS:

A soil fungus that assimilates numerous aromatic or polycyclic hydrocarbons.

A worldwide distribution, but mainly found in human-impacted areas such as industrial areas, city parks, roadsides, and farming lands

Highly semiselective culture media are available for the detection of *Scedosporium* species.

The first genome sequence of *S. apiospermum* (43.4 Mbp; 10 919 predicted genes) was published in 2014.

DISEASE FACTS:

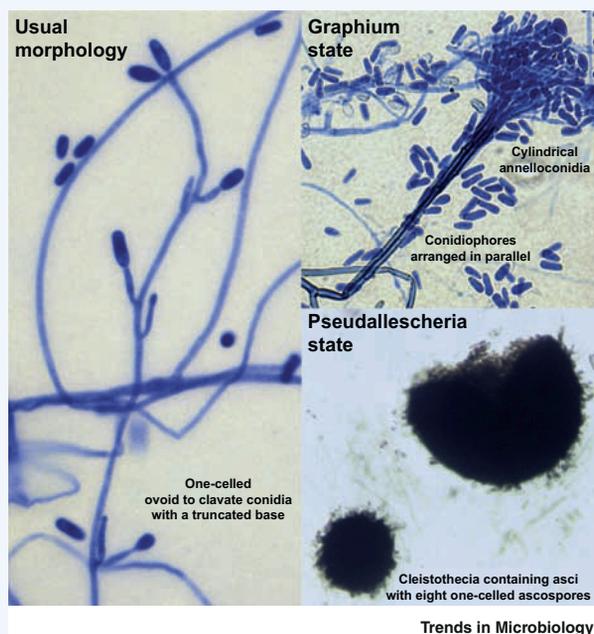

S. apiospermum may cause various human infections ranging from localized infections such as subcutaneous and bone or joint infections, to severe and often fatal disseminated infections in immunocompromised hosts.

This old pathogen has recently gained increasing attention because of its worldwide recognition as a significant pathogen in CF.

Colonization of CF airways constitutes a major risk factor for a disseminated infection in the case of lung transplantation, and all efforts should be made to detect the airway colonization as early as possible and to eradicate the fungus, particularly at registration on the transplantation waiting list.

The limited susceptibility of this fungus to current antifungals justifies work aiming to elucidate its biology and pathogenic mechanisms, which has already led to the identification of some promising targets for drug development, for example, enzymes involved in uridine synthesis, acylation of inositol, nonribosomal peptide (NRP) synthesis, or detoxification of reactive oxygen species.

Usually a soil saprophyte, *Scedosporium apiospermum* is one of the major pathogenic *Scedosporium* species. Beside chronic localized infections resulting from traumatic inoculation of some soil fungal elements, this cosmopolitan filamentous fungus may also cause respiratory or disseminated infections through inhalation of conidia, particularly in patients with hematological malignancies, solid organ transplant recipients, and patients with cystic fibrosis (CF). With a frequency ranging from 3.5 to 11.7%, *Scedosporium* species rank second among the filamentous fungi chronically colonizing CF airways. Although well tolerated in most cases, this airway colonization may lead to bronchitis or allergic bronchopulmonary mycoses, but also to disseminated infections in patients undergoing lung or heart-lung transplantation. Here we summarize the recent advances on the mechanisms allowing the fungus to evade host immune defenses and to establish a chronic respiratory infection.

TAXONOMY AND CLASSIFICATION:

- KINGDOM:** Fungi
- PHYLUM:** Ascomycota
- CLASS:** Sordariomycetes
- ORDER:** Microascales
- FAMILY:** Microascaceae
- GENUS:** *Scedosporium*
- SPECIES:** *apiospermum*
